ABSTRACT

This study investigated the use of terrestrial **haulout** sites in the eastern Bering Sea by four species of pinnipeds, northern fur seal, northern sea lion, harbor seal and Pacific walrus. Historical information on the use of each site was summarized. For a few sites there was little or no information about the number of animals present and consistency of use of the site, so we were unable to properly evaluate these.

Available information on the effects of airborne and waterborne noise, and human disturbance (from stationary and moving sources) was reviewed. We also conducted a detailed analysis of the acoustic environment of eight **haulout** sites. These eight sites were representative of others used by each of the four species studied. The analyses included investigations of (1) characteristics of airborne and underwater ambient noise, (2) characteristics of industrial noise sources, including aircraft, small boats, fishing trawlers and commercial cargo traffic, and (3) sound transmission loss in air, water and through the air-water surface.

Inter-site Population Sensitivity Index (IPSI)

As a means to evaluate the potential vulnerability of each **haulout** site to noise and disturbance, we developed a quantitative rating system (**IPSI**) whereby an index of sensitivity was assigned to each site. **IPSI** values were computed from rank scores assigned to eight categories associated with each site occupied by each of the four pinniped species. The eight categories were (1) the peak count of a particular species of pinniped recorded at a site since 1980, (2) the mean maximum number of animals recorded at a site during the past three decades and during the most recent count at the site, (3) the proportion of the current total estimated Bering Sea population present at a **particular site**, (4) the age and sex composition, and the kinds of behavioral activities that have been recorded at a site, (5) the duration of use of a **haulout** site, (6) consistency of use of a **haulout** site, (7) various physical characteristics of the site, including substrate type, local relief, water depth and proximity to airports, shipping **lanes**, human settlements, and (8) species characteristics, i.e. susceptibility of animals of this species to

noise and disturbance and the potential for mortality. Sites that rated high had high IPSI scores and were considered most sensitive.

Norton Basin Planning Area

There are **14 haulout** sites in this planning area; they are used by two of the four species of pinnipeds studied. No northern fur seals or harbor seals haul out in significant numbers here. Twelve of the 14 sites are used by Pacific walrus. Two haulout sites, the one on North Penuk Island, and the one on King Island ranked high in our IPSI evaluation scheme. Northern sea lions have occasionally hauled out at Southwest Cape on St. Lawrence Island and on nearby South Penuk Island. However, there is no current information concerning the use of these sites by sea lions.

St. Matthew-Hall Planning Area

In this planning area 24 haulout sites are used by three of the four pinnipeds studied; there are no northern fur seal haulout sites in this area. Most of the sites (11) are used by northern sea lions, however none ranked high in the overall IPSI evaluation scheme. Pacific walrus sites were second in abundance (8) and four of these, all on St. Matthew or Hall islands, ranked high. Harbor seal sites were least abundant (5) in this planning area, but the site(s) in Kuskokwim Bay ranked relatively high. This area, and the areas to the east near Avinof Point, may be the most northerly major harbor seal pupping areas in the eastern Bering Sea.

North Aleutian Basin Planning Area

This planning area contains 44 haulout sites used by three of the four species studied; no northern fur seals haul out in this planning area. Harbor seals used 22 of the sites including 9 (20%) that rated high in our IPSI evaluation scheme. Twelve sites were occupied by northern sea lions, and at least six (14%) of these were ranked high. Ten sites are occupied by Pacific walrus, and five (11%) of these were ranked very high.

St. George Basin Planning Area

This planning area has 54 **haulout** sites used by three species; this is the largest number of **haulout** sites in any of the four planning areas in the eastern Bering Sea. There are no consistently used Pacific walrus **haulout** sites, but all 22 northern fur seal **haulout** sites in the eastern Bering Sea are found here (**Pribilof** Islands and **Bogoslof** Island). Seventeen sites are occupied by northern sea lions, and 6 (11%) of these were ranked very high in our **IPSI** evaluation scheme. At least 15 sites are used by harbor seals, and three (6%) of these (two in the Fox Islands and one on Otter Island) were ranked very high.

Overall, we evaluated 120 of 136 terrestrial haulout sites in four different OCS Planning Areas in the eastern Bering Sea. Of the 44 sites in the North Aleutian Basin Planning Area, almost half (20 sites; 45%) ranked high in our **IPSI** evaluation scheme. This number represents almost half of the total 41 most highly rated sites in the study area. Of the 54 sites in the St. George Basin Planning Area, 19 (35%) were rated high; this number was strongly influenced by 10 highly ranked northern fur seal sites on the **Pribilof** Islands. Of the 24 sites in the St. Matthew-Hall Planning Area, 5 (21%) rated high in our **IPSI** evaluation, and most (4 of 5; 80%) were sites occupied by Pacific walrus. Of the 14 sites in the Norton Basin Planning Area, only 2 rated high in our **IPSI** evaluation; both of these sites were occupied by Pacific walrus.

ACKNOWLEDGEMENTS

Many people helped us complete this study. In particular, we thank the biologists, and resource and information specialists with state and federal agencies in Alaska, Washington State, and Canada. Those at the National Marine Mammal Laboratory (NMML), National Marine Fisheries Service (NMFS), Seattle, who helped are Bud **Antonellis**, Chuck **Fowler**, Roger Gentry, Biro **Kajimura**, Tom **Loughlin**, Rick **Merrick** and Ann **Yorke**. We especially thank Sherry Pearson, information specialist at the NMML library for allowing us free access to files and publications. Hiro **Kajimura** gave us updated maps of northern fur seal rookeries and haulout sites on the **Pribilof** Islands. Peter **Boveng**, NMFS Southwest Fisheries Center, Ja Jolla, provided recent reports on the status of the harbor seal and fur seals.

Those with the Alaska Department of Fish and Game (ADFG) who helped are Glen Seaman in Anchorage, Kathy Frost, Lloyd Lowry, and Chris Smith in Fairbanks, Ken Taylor in **Dillingham**, and Dick Seller's in King Salmon.

The following people at the U. S. Fish and Wildlife Service (USFWS) also helped: Scott **Schliebe** in Anchorage, Sue Hills in Fairbanks, Dave Fisher in **Dillingham**, Randall **Wilke** in King Salmon, Chris Dau in Cold Bay, and Art **Sowls** and Tom Early in Homer.

Mike **Bigg**, with the Department of Fisheries and Oceans (DFO), **Nanaimo**, British Columbia, provided access to the extensive reprint collection at the Pacific Biological Station. Information specialist Gordon Miller also helped find important papers and reports at the DFO library in **Nanaimo**.

Various people at LGL also helped during this study. Dale Herter (LGL Alaska, Anchorage), Dave **Roseneau** (LGL Alaska, Fairbanks), Bill Koski and John Richardson (LGL Limited, King City) and Kerry **Finley** (formerly LGL Limited, Sidney, B.C.) provided relevant literature and information concerning the effects of noise and disturbance on **pinnipeds**. We also thank Greg Green, **Envirosphere** Co., **Bellevue**, Washington, who gave us unpublished information on sea lions.

Steve Treaty, Minerals Management Service (MMS), Anchorage, Alaska, helped set the geographical limits to the study area, and arranged for us to get official protraction diagrams of the coast and islands of the eastern Bering Sea. We thank Steve for his patience and cooperation throughout this study.

INTRODUCTION

Background

In Alaska four species of pinnipeds congregate, often by the thousands or tens of thousands, at specific terrestrial **haulout** sites along island and mainland coasts of the eastern Bering Sea. These species are the northern fur seal (Callorhinus ursinus), northern or Steller sea lion (Eumatopias jubatus), harbor seal (Phoca vitulina richardsi) and Pacific walrus (Odobenus rosmarus divergens). Except for the walrus, these species may **occupy** terrestrial **haulout** sites during pupping, nursing, mating and molting, which are all potentially times of elevated stress. (Mating, pupping and nursing by Pacific walruses occurs during January through June in the pack-ice rather than at terrestrial sites.) Consequently, acoustic and/or visual disturbance of animals at terrestrial **haulout** sites could adversely affect these and other functions, or could further decrease resistance to parasitic infection, thermoregulatory impairment, disease and other stress factors.

In recent years, the northern fur seal, northern sea lion and harbor seal populations in the North Pacific region including Bering Sea have experienced significant declines. These declines have been attributed to a variety of causes, e.g., entanglement in abandoned or discarded fishing gear, disease and parasitic infections, and reductions (principally through overfishing) in the abundance of principal prey species. However, there have been few studies of the potential sensitivity of these pinniped species to industrial disturbance near **haulout** sites. Additionally, although the Bering Sea population of the Pacific walrus has increased markedly in the past decades, mass mortality has occurred at some locations, and it has been suggested that this species may be sensitive to certain vessel and aircraft traffic.

Literature exists which identifies Bering Sea **haulout** locations for the four pinniped species. However, site-specific population information has not been combined with known behavioral and acoustic information to describe the potential for disturbance of these four pinniped species by oil and gas development activities in the Bering Sea. The present study was conducted on behalf of the U. S. Department of Interior, Minerals Management Service, in

anticipation of eventual oil and gas exploration and development on the Outer Continental Shelf of the eastern Bering Sea. The purpose of this study was to provide an up-to-date and comprehensive synthesis of available information of the known and expected effects of (1) underwater noise, (2) nearby vessel traffic, (3) low-flying aircraft and (4) other associated human disturbances on major concentrations of northern fur **seals**, northern sea **lions**, harbor seals and walruses at rookeries and **haulouts** in the eastern Bering Sea.

Objectives

The principal objectives of this investigation. were as follows:

1. Summarize the literature and compare the year-round utilization of major Bering Sea **haulout** sites **by** northern **fur seals**, northern sea lions, harbor **seals and** Pacific walruses. This objective included (a) a review of available literature **on** the distribution of the four pinniped species in the Bering Sea adjacent to Alaska, (b) the identification of the major **haulout** sites for these **species**, (c) an analysis of the use of major **haulout** sites by different age and sex **cohorts**, and (d) a summarization and **estimation** of the year-round use and relative biological **value** of each major **haulout** site to each species.
2. Summarize and quantify available information on the effects of industrial disturbances on the four major species being studied. This objective included (a) a summary and comparison of available information on the immediate and long-term effects of acoustic and **visual** disturbance **on** individuals and on concentrations (**haulout** sites) of the four species of pinnipeds, (b) **a** discussion of the applicability of information available for other pinniped species, and (c) a review of responses of marine mammals to various acoustic stimuli.
3. Based on data obtained in **1** and **2** above, estimate the relative vulnerability of the major **haulout** sites to industrial disturbances.
4. Assess whether disturbance to specific **haulouts** may have population-level effects on the above mentioned four species.
5. Conduct an analysis of the acoustic environment of representative pinniped **haulout** sites.

Study Area

The study area for this project is the Bering Sea adjacent to Alaska (Fig. 1) including the mainland coast from Cape Prince of Wales in the north to Cape **Krenitzin** at the tip of the Alaska Peninsula, in the south. It also includes all of the islands in the Bering Sea from Little Diomede Island in the north (in Bering Strait) to Unimak Island and the Fox Islands in the eastern Aleutian chain. Umnak Island is the most westerly island considered in detail in this review.

Some information from haulout sites on the Pacific Ocean sides of some of the Fox Islands (i.e., Ugamak I., Aiktak I.) are also considered. In general, however, we have restricted our investigations to **haulout** sites on the Bering Sea sides of the eastern Aleutian Islands.

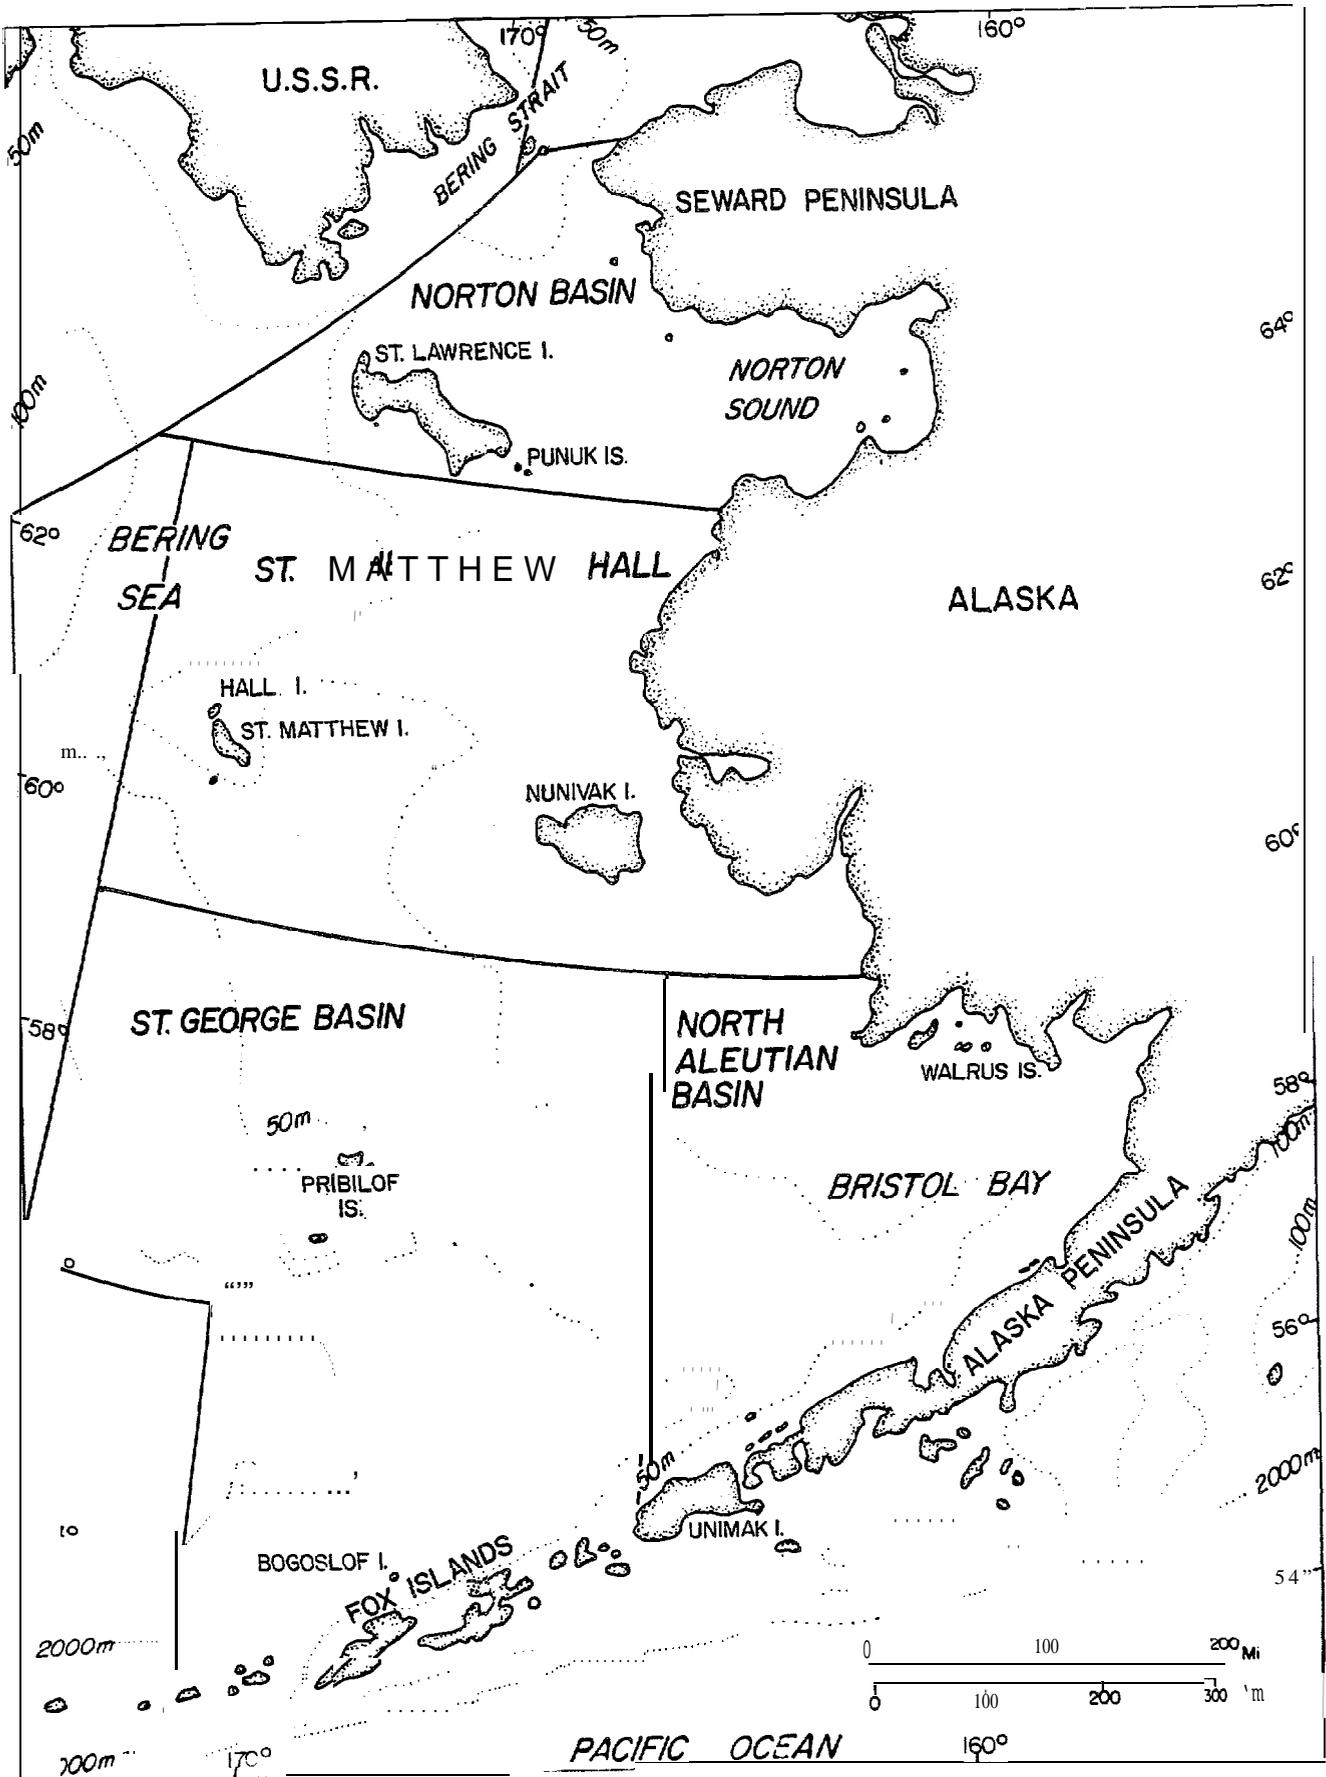

Figure 1. Map of Bering Sea, Alaska study area showing OCS planning areas.

METHODS

Terminology

Throughout this report we use the terms 'haulout site', 'rookery', and 'hauling ground' or 'haulout'. These terms refer to any site where pinnipeds traditionally haul themselves out of the water; however, the terms are not used synonymously. Haulout sites are composed of 'rookeries' and 'hauling grounds' (or 'haulouts'), which serve different biological functions for northern fur seals, northern sea lions, and other eared seals.

For northern fur seals, rookeries are areas generally near the water where females have their pups, where males and females congregate to breed, and where pups are raised. Hauling grounds are generally located near the rookeries but are more inland, and are occupied by non-breeding individuals during the breeding season. Some **adult** males may move to hauling grounds after the breeding season.

Similar to northern fur seals, northern sea lions give birth, nurture their pups, and breed at traditional, well established rookeries. Hauling grounds are often adjacent to the rookeries and are occupied by non-breeding or "bachelor" males (3+ years of age), and later by harem bulls. Bachelor **bull** northern sea lions aggregate at hauling grounds and spend much of their time mock-fighting or making occasional trips into the rookeries where they are chased by resident males. Unlike fur seals, northern sea lions haul out throughout the year, rather than only during the breeding season. In the present report we make a distinction between northern sea lion rookeries (breeding/pupping areas) and **haulouts**.

Harbor seals often congregate to feed and give birth at traditional sites, but these sites do not fit the definition of a rookery as described above, i.e. , where males have well established territories in which females are defended and bred, and pups are born.

Walrus (mainly males in the present study) haul out at traditional terrestrial sites **in the** study area, but these sites are not rookeries; few females are present at terrestrial sites in the Bering Sea except **in** the far north during late **fall**. During this period, **males** may fight over **females**, but virtually all breeding and pupping occurs **in** the pack-ice during **late** winter through spring. The 'Glossary' provided **in** Appendix 9 gives more details and documentation of terminology used in this report.

Review and Summary of Information on
Pinniped Populations and Disturbance

Initially we conducted a search of data bases such as **ASFA** (Aquatic Sciences and Fisheries Abstracts), **ASTIS** (Arctic Science and Technology Information Service), **BIOSIS** Previews (Biological Abstracts) and **NTIS** (National Technical Information Service). We **also** conducted thorough searches for relevant information in libraries at (1) the **U. S.** National Marine **Mammal** Laboratory (Nat. Mar. Fish. **Serv.**, NOAA, Seattle, WA), (2) the Pacific Biological Station (**Dept.** Fish. and Oceans, **Nanaimo, B.C.**), (3) the University of British Columbia, Vancouver, **B.C.**, (4) the various offices of **LGL** Limited (King City, Ontario; Sidney, B.C.) and **LGL** Alaska Research Associates (Anchorage and Fairbanks, Alaska), (5) office and staff libraries of the **U. S.** Fish and Wildlife Service **in** Alaska (Anchorage, Fairbanks, King Salmon, **Cold** Bay, **Dillingham**) and (6) office and staff libraries of the Alaska Dept. of Fish and Game (Anchorage, Fairbanks, King Salmon, **Dillingham, Nome**). **Important** sources of valuable information for this study have been personal communications from people who are currently working or have in the past worked extensively with pinnipeds in the Bering Sea and elsewhere.

We summarized pinniped population information for each major haul out site, i.e. with a few exceptions, a site where at **least 1%** of the total population had been recorded since 1950. Since populations of some species have fluctuated greatly in the past 2-3 decades, and no doubt will continue to do so in future years, we decided that it was not justifiable **to** exclude a **haulout** site because it had not been used in the past 10 years.

Counts at **haulout** sites may be influenced by a large number of factors, e.g., time of year, time of day, weather conditions, visibility, type of observation platform (aircraft, ship, boat, land), count procedure, observer ability, disturbance levels at sites, and nature of survey (opportunistic or otherwise). Counts at some sites on the same day may fluctuate from several thousands (or tens of thousands) of individuals to virtually none. As noted in most summary tables in this report, counts of northern sea lions, harbor seals, and Pacific walruses are from many different sources, and many data have not been collected in a systematic or consistent manner (data for the northern fur seal are an exception). For this reason, in our main summary tables we present peak counts at each site for each of the four decades since the 1950's (Frost et al. 1983 used a similar approach), as well as the most current count and year of most current count for each site; details of all other individual counts are given in Appendices 6 through 8. In many cases, the most current count is often significantly lower than the peak count for the 1980's (because of recent regional population declines). When available, we give a breakdown by age and sex.

Inter-site Population Sensitivity Index (IPSI)

The importance and vulnerability to disturbance, i.e. the sensitivity of each **haulout** site used by each of the four species, was computed and an **Inter-site Population Sensitivity Index (IPSI)** was generated for each site using a series of variables or factors related to (1) the location and major physical characteristics of the **haulout** site being considered, (2) the status, composition and trend in numbers of the population being considered, and (3) the species being considered and its general response to disturbance (based on the literature). These variable factors and the way they fit into the **Inter-site Population Sensitivity Index (IPSI)** are described in more detail below.

The eight variables associated with each species and each site were ranked on an integer scale (1 through n) according to the total number of sites (n) considered for the species in question. Where variables (or factors) at two or more sites were of equal importance, they were treated as ties (ranked equally). In instances where two factors were highly interdependent, they were pooled into a single complex factor in order to reduce bias. It

should be pointed-out, however, that most of the variables considered in this analysis were to some degree dependent on one or more of the other variables; it was not possible to eliminate **all** redundancy and/or bias in this ranking procedure. Thus, because of inherent unavoidable biases, the evaluation procedures that we used **should** not be considered a rigorous statistical treatment.

A mean rank was computed from the rank scores for each **site**. These means were then ranked again to determine the overall Inter-site Population Sensitivity Index (**IPSI**) for each site considered. For example, **if** there were 25 **haulout** sites described for a particular species of pinniped, then **the** site with the lowest overall mean rank (based on currently available information) had the highest **IPSI score--i.e.**, was considered a site where severe disturbance **could** cause population-level effects.

Important variables **or** factors considered in evaluating each site were as follows:

1. The peak count of a particular species of **pinniped** recorded at a **site** since **1980**. This peak emphasizes the most current counts (**1980's** count and the most current count) at a particular site. Peak count data for northern **fur** seal, northern sea lion, harbor seal and Pacific walrus are from Tables 3, 5, 6 and 7, respectively.
2. The mean maximum number of animals recorded at a **site** during **the** past three decades and during the most recent count **at** the site. This provides an indication (but **only** an indication) of the degree of use **of** the site over the past 30 years. The **values given in** Tables 8 through 11 are based on the average of peak counts for each of the 1960's, 1970's, 1980's, and the most current count at the sites given in Tables 3, 5, 6 and 7. Data from the 1950's, although presented in many of the review tables in order to provide historical perspective, have not been included in the evaluation scheme.
3. The proportion of **the** current **total** estimated Bering **Sea** population present at a particular site. A site that supports a large percentage of the population is considered more important than a site that supports **only** a **small** percentage. The values given in Tables 8 through 11 are the proportions based on current counts, *i.e.*, the most current count recorded since 1980 and the most recent population estimate given in Tables 3, 5, 6 and 7, respectively.

4. Age and sex composition, and the kinds and amount of behavioral activities that have been recorded at a site. A large and complex site that is used for pupping and nursing, and for breeding was considered to be more important to a species and potentially more sensitive than a small site or a site used only for resting, or only by **subadults**. This factor therefore actually includes several important variables-- (1) age/sex composition and complexity of the site, and (2) behavior-- and both are highly interdependent. Information on the age/sex composition (and thus behavior), and complexity (number of subdivisions and areal extent) of the site are given in Tables 3, 5, 6 and 7, and in Figures 13, 14, 15 and 16, respectively.
5. Duration of use of a **haulout** site. A site that is used for a large part of the year is considered to be more important and more vulnerable than a site used only intermittently (e.g., only during migration) . Since sites that are used for a large part of the year often are the rookeries, where various age and sex classes and a variety of different behaviors are exhibited, this variable is obviously related to several of the other variables. Duration of use was computed for each species using information given in the literature; e.g., Table 2 for northern fur seal where virtually all sites have rookeries and are occupied for about seven months (0.583 yr). Only some northern sea lion sites are rookeries or are near rookeries, which are occupied for an extensive period (0.500 yr, Table 3). Other southern Bering Sea sites may be used for about 0.250 yr and more northerly sites are used for only 0.167 yr (see Table 9). Harbor seal sites are also occupied for various durations depending on their geographic location and the average position of the ice front during winter. Southern sites are occupied by seals all year while the northerly sites are occupied for only about six months (0.500 yr, Table 10). Similarly, Pacific **walrus** occupy sites for various periods depending on the sex and age composition of the animals and the location of the site (Table 11). Southern sites are used almost exclusively by males for periods ranging from 2 to 7 months (0.167 to 0.580 yr). Northerly sites may be used by **all** ages and sexes for periods ranging from 2 to 4 months (0.167 to 0.333 yr).
6. Consistency of use of a **haulout** site. A site that is used every year is considered to be more important and more vulnerable than a site that is used only sporadically. Rookeries are used most consistently from one year to the next; thus, there is a strong relationship between consistency of use of a site and the **age/sex classes**, behaviors and duration of use of a site. Consistency of use of a site is determined by the frequency with which animals are recorded at sites during different surveys over a period of years.
7. Site characteristics, i.e., the physiography and associated susceptibility of the site to disturbance. This factor is based on the major physical characteristics of the site, e.g., the substrate, vertical relief, bathymetry, etc., in the immediate vicinity of the site, and its proximity to sources of disturbance. Any site located within 5 km of a source of noise or disturbance (shipping lanes, airports and/or air traffic lanes, settlements, etc.) was ranked **high**

in our evaluation scheme. Other sites not located close to noise or disturbance sources were ranked in accordance with the physical characteristics of the site.

8. Species characteristics *v.e.*, susceptibility of a species to disturbance. This factor is based on how the species responds to disturbances of different types (based largely on the literature presented in this report). It is dependent to a degree on the composition (age/sex, behavior) of the animals present at the site, how that segment of the population is affected by disturbances, and whether or **not** there is a high, medium or low probability of mortality as a direct or indirect result of noise/disturbance. Species that are known to have suffered mortality as a result of noise/disturbance (e.g., Pacific walrus, northern sea lion, harbor seal) were ranked high, and others (e.g., northern fur **seal**) were ranked **lower** (Tables 8 through 11).

Analysis of the Acoustic Environment

We also conducted a separate analysis of the acoustic environment of eight **haulout** sites (see Appendix 1). These sites were considered to be representative of those used by each of the four pinniped species considered in the present study. The physical conditions (location in the study area, proximity to noise sources, site substrate, slope of beach and sea **bottom**, bottom type), and pinniped use of these eight sites were included in our selection criteria. The analyses included investigations of the following topics:

1. Characteristics of airborne and underwater ambient noise.
2. Characteristics of industrial noise sources, including aircraft, **small** boats, fishing trawlers and commercial cargo traffic.
3. Sound transmission loss in air, water and through the air-water surface.

The ambient noise characteristics of the sites were estimated using data obtained from studies of similar areas. The noise source characteristics were obtained from data reported in the literature and data in the archives of BBN Systems and Technologies Corporation. Transmission loss characteristics for airborne and underwater sound were estimated using standard analytical procedures and computer models (see Appendix 1). An analytical procedure was developed for prediction of transmission of sound from aircraft into shallow

water, since an existing procedure was not available. Procedures are described for using the information obtained in this study to predict noise exposure levels and to develop 'zone-of-influence' estimates for the various species of concern. All of these procedures are described and discussed in detail in Appendix 1.

RESULTS

The following results are presented in several sections, in accordance with the general objectives of the study. The first sections give descriptions of important background life-history information about each of the four species, information about patterns of occupancy and history of use of key **haulout** sites, and information about the location and status of **haulout** sites for each of the four species in **the** eastern Bering Sea. Later sections (1) review information on the effects of disturbance and noise on **pinnipeds**, and (2) review information on acoustic processes that may be relevant to OCS development near pinniped **haulout** sites in the eastern Bering Sea (Appendix 1). Specific descriptions of the physical characteristics and maps of each major **haulout** site are given in Appendices 2 through 5.

Northern Fur Seal (*Callorhinus ursinus* L.)

Background

The northern fur **seal** belongs to the family of eared **seals** (**Otariidae**); it is a medium-sized pinniped with adult bulls in prime condition on their breeding territories measuring about 2-3 m in **length** and weighing between 135 and 280 kg. Northern fur **seals** remain at sea for most of the year, often far from shore along the continental **shelf** and **slope**. The distribution of northern fur **seals** in the Pacific is from the Bering Sea to Southern California and Japan (**Fowler 1985, In press**). Figure 2 shows the general distribution of this species in the eastern Bering Sea.

No individual fur seal older than a neonate spends longer than 60-70 days of the year on shore (Gentry 1981). Males reach sexual maturity by about 6 years of age and females by 4-5 years of age; they give birth to a **single** pup (very **rarely** twins) weighing 4.5-5.5 kg each year. Adults may **live** to be almost 25 years of age (**Fowler 1985, In press**).

Northern fur seals are the most abundant marine mammal in the Bering Sea, but recent declines have occurred throughout its range. The current worldwide population of 1,173,000 is significantly **less than** the" 1,765,000 individuals

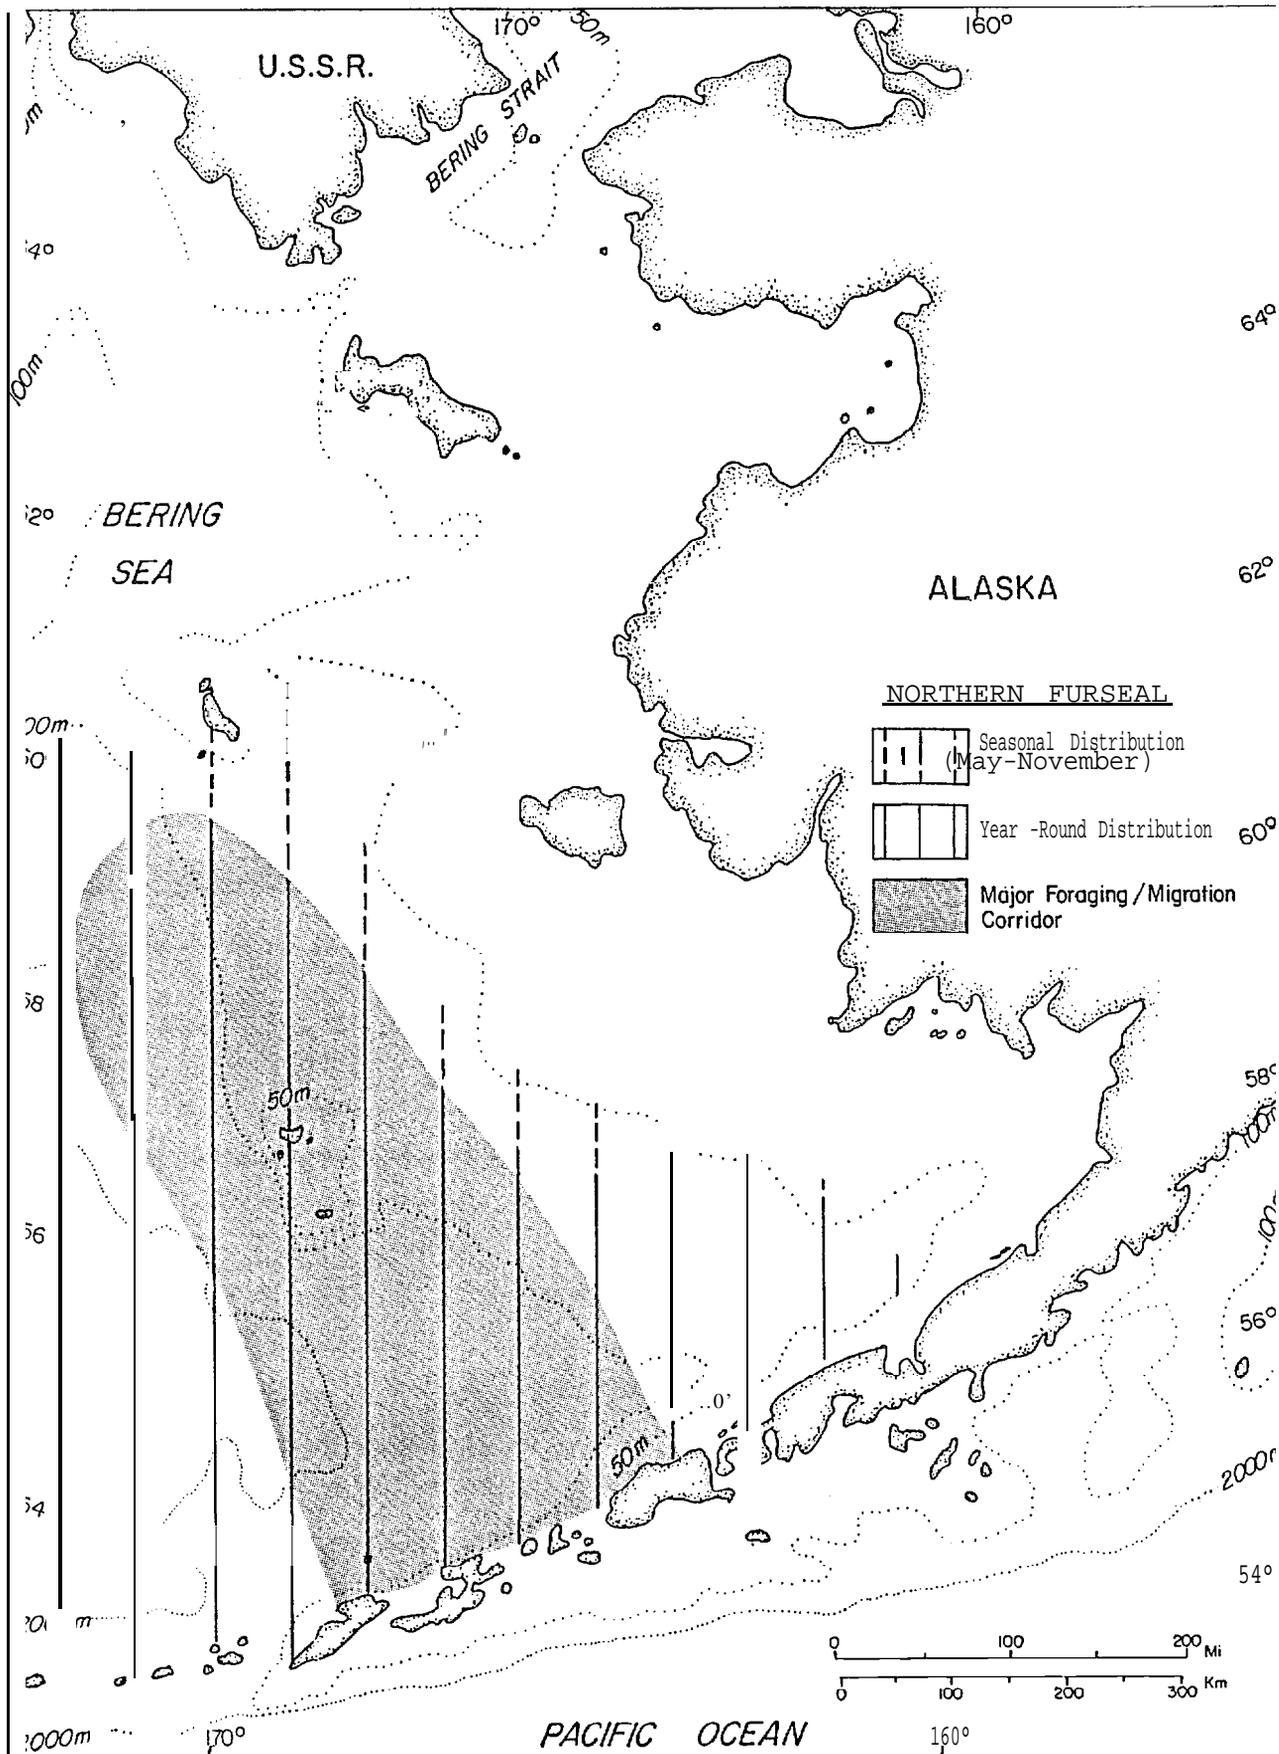

Figure 2. General distribution of the northern fur seal in the Bering Sea, Alaska.

reported in **the** mid 1970's by Lander and **Kajimura** (1982). Similarly, the number of fur **seals** estimated on the **Pribilof** Islands has declined from 1.3 million in the mid-1970's (Lander and **Kajimura** 1982), to 0.9 million in the mid-1980's (North Pacific Fur Seal Commission 1984, cited in Bigg 1986:383), to **the** current estimate of about 0.8 million individuals. This represents a decline since the **mid-** to **late 1970's** of about 4-8% per year (average = 6.1%; **Fowler 1985**). Recent studies indicate that the decline may in part be the result of increased mortality of younger age classes through entanglement in abandoned and **lost** fishing gear and other debris (**Fowler 1984, 1985, 1987, In press; Yoshida and Baba 1985**). Because of the decline, the National Marine Fisheries Service recently (May 1988) listed the **Pribilof Islands** population of northern fur **seals** as a 'depleted **species**' under terms of the Marine Mammal Protection Act of 1972 (**MMPA**).

Fur seals come ashore at several important locations in the North Pacific, Bering Sea and Sea of Okhotsk, though mainly during and after the breeding season (May-November). The distribution of northern fur seal haulout sites (rookeries and hauling grounds) in the eastern Bering Sea is limited to the **Pribilof** Islands including Sivutch (**also** known as Sea **Lion Rock**) and **Bogoslof** Island (Fig. 3 and Appendix 2) which are used by about 70-74% of the **world** population of this species. This relatively restricted distribution of haulout sites is thought to **be** related to nearby oceanographic features. **Lloyd et al. (1981)** speculated that the feeding habitats of **all** fur seals, not just those in the Bering Sea (**Perez 1979, Perez and Bigg 1980**), consist of the outer continental **shelf** and oceanic **domains**, and that "**only** islands in or immediately adjacent to the [very productive and food-rich] outer shelf domains are suitable for fur seal rookeries."

Patterns of Occupancy at Haulout Sites

Bigg (1986) conducted a detailed investigation of the rather **complex** patterns of arrival and departure of northern fur seals at haulout sites on St. **Paul Island** in the **Pribilofs** (see discussion above). Arrival and departure patterns on St. Paul probably are also representative of arrival and departure patterns on St. George Island, also in the **Pribilofs** (**M. Bigg, pers. comm. 1987**). Northern fur seals occupy **haulout sites** at different times depending on

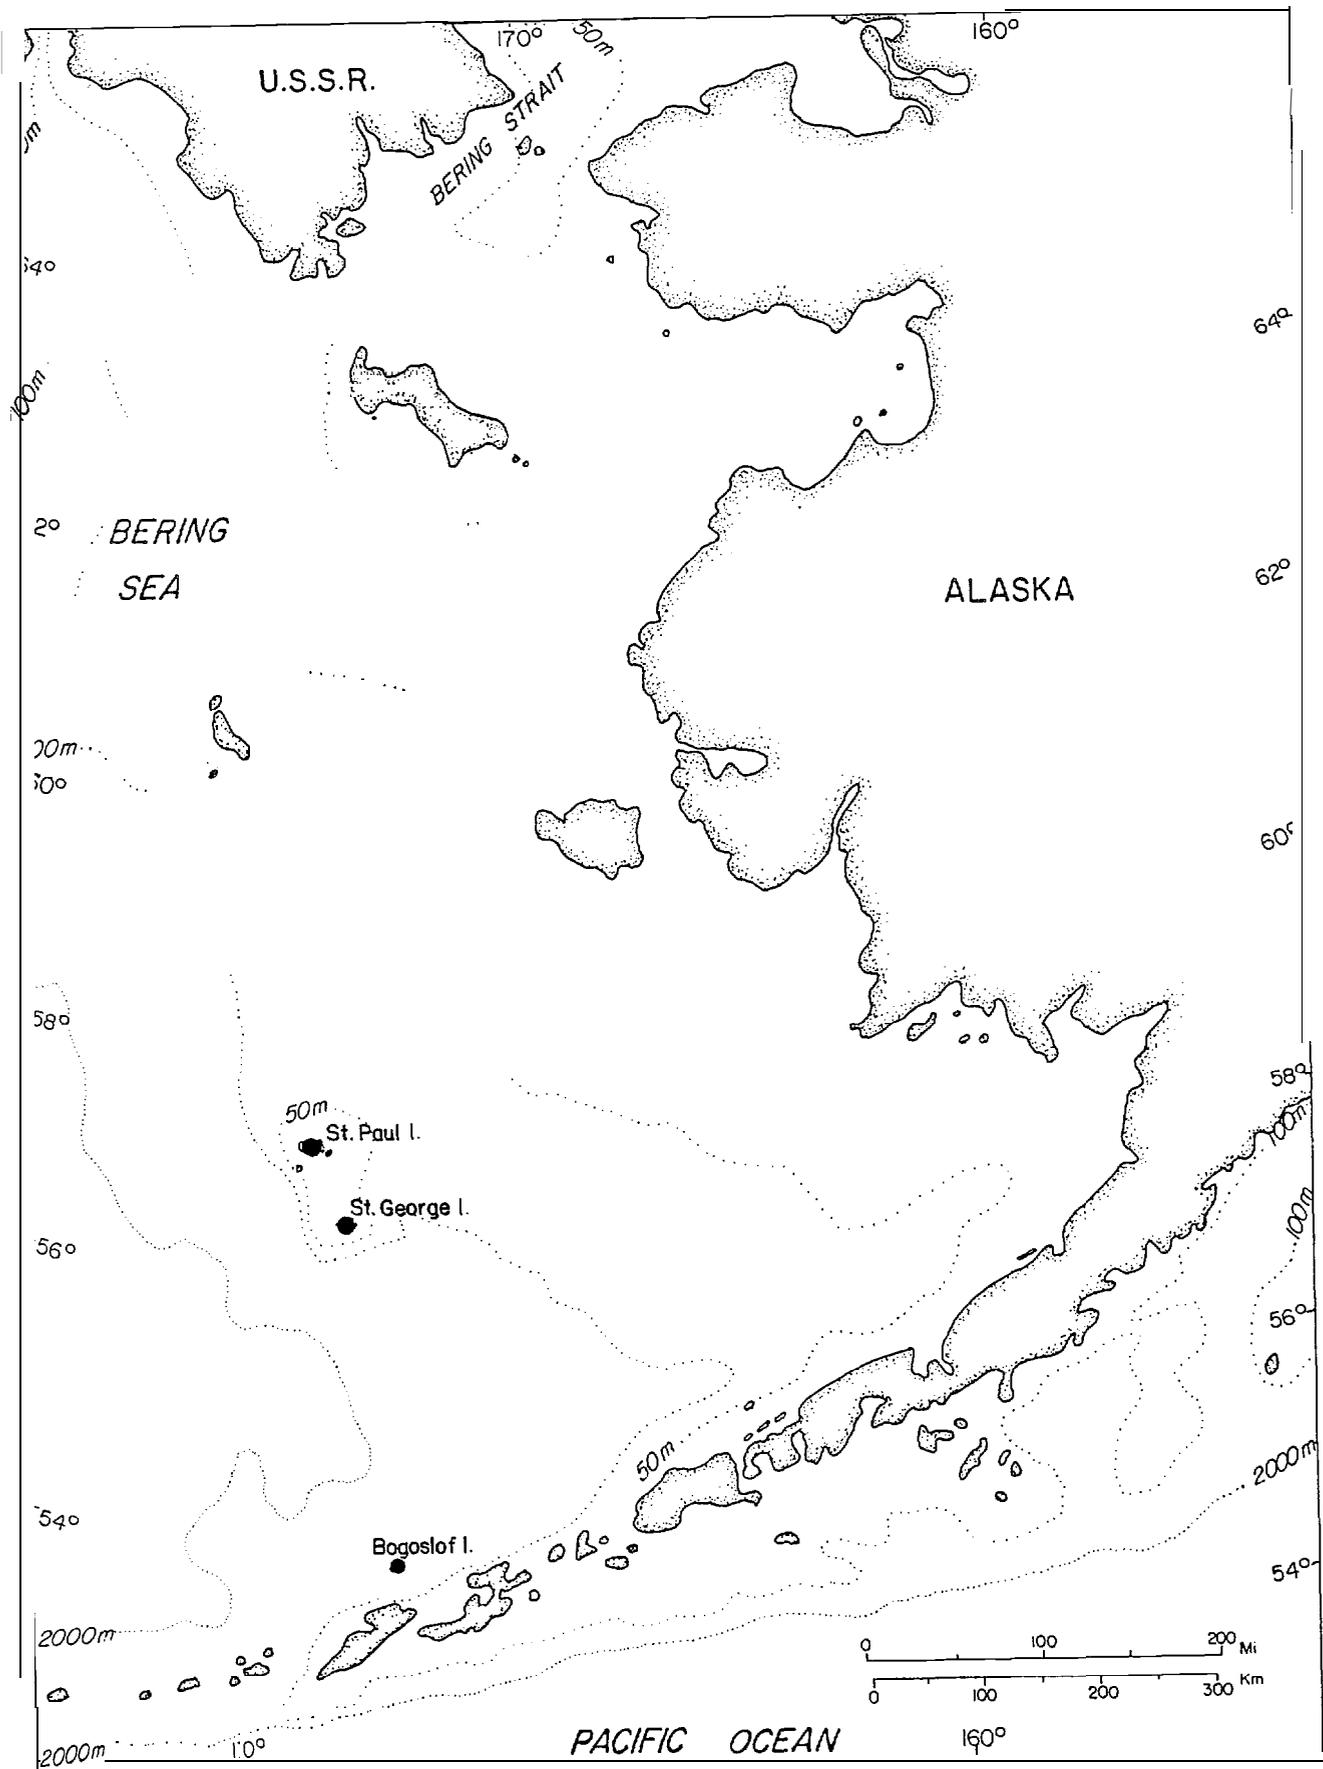

Figure 3. Locations of northern fur seal haulout sites in the Bering Sea, Alaska.

their sex and age. In general, the oldest and strongest bulls return **first**, followed by younger **bulls** and **adult** females, followed by even younger **bulls** and females (Table 1). The first bulls begin arriving at **Pribilof Island** rookeries in **early** to mid-May and usually abandon their territories by mid-August. Pregnant females begin arriving in mid-June. Females usually give birth within a day of arriving at the rookery, but it is not unusual for some females to give birth up to three days after arriving. The peak of pupping is in early **July (Fiscus 1986)**. Pups are nursed until the **female** breeds 5-6 days after giving birth (Gentry and Holt 1986). Females then return to sea to feed for several days (mean 3.5 days, Loughlin et al. 1987). This is the first period of feeding by females after their arrival **at** the rookery. The female continues to come and go to and from the rookery for about **120** days (Gentry and Holt 1986). She travels to sea for periods averaging **5.7** days in July and 7.3 days in August; each feeding period is followed by two days of nursing (mean 1.9-2.2 days according to Loughlin et al. 1987 and Gentry and Holt 1986,

Table 1. Summary of the timing of arrival of hauling grounds and rookeries by northern fur **seals** of different ages and **sexes**, **St. Paul** Island, Bering Sea, **Alaska** (from Bigg 1986).

*** Date when essentially all **seals** have arrived.

respectively). This process continues until the pups are weaned. Adult females start to leave the rookeries in early October (Gentry 1981) and departure continues into November (Table 2). Pups first enter the sea at about 4-6 weeks of age, but may remain at the rookery until early November (Fiscus 1986).

Table 2. A summary of the occupancy of **haulout** sites on the **Pribilof** Islands, Bering Sea, Alaska, by different age and sex classes of northern fur seals.

* '1' in the time line indicates the approximate earliest dates of arrival, '2' indicates the approximate date of abandonment of territories by adult bulls and breakdown of the social structure of the rookery, and '3' indicates the beginning of the departure of fur seals from the islands and the start of the southbound migration.

The 3 to 5-year-old males begin to haul out on the hauling grounds in late June, and younger animals continue to arrive well into September. The latest arrivals include many 2-year-olds. Although most yearlings remain at sea and do not return to **haulout** sites, a few yearling females may make brief visits to the periphery of rookeries or hauling grounds as late as early November.

Location and Status of Northern Fur Seal Haulout Sites

Pribilof Islands

St. Paul Island. There are 14 distinct **haulout** sites (rookeries with associated hauling grounds) on St. Paul Island (Table 3; Appendix 2; Kozloff 1985). The history of use of these **haulout** sites (Table 3) shows a general decline in the number of breeding bulls and pups since the 1950's. The most

Note: data in this table are from many different years and may not have been collected in a systematic manner.

* 1950's, 1960's and 1970's data are from Lander (1980).

** 1980's and 'Current' data are from Lloyd et al. (1981), Kozloff (1986) and NMFS files.

† Estimates of pup production are based on the ratio--Breeding Bulls:Pups= 1:34.35 (Kozloff 1986:11).

†† Recent annual pup production on Sivutch (Lander and Kajimura 1982:322).

• Est. of recent annual Breeding Bulls on Sivutch are based on the ratio - Breeding Bulls:Pups =1:34.35 (Kozloff 1986:11).

current estimates indicate that about 124,500 pups (plus at least the same number of adult females) and about 3600 harem bulls used these 14 haulout sites during 1987 (NMFS file data).

Sivutch. This haulout site is located on a small island about 0.5 km S of St. Paul Island (S of the rookery at Reef; Appendix 2). Jordan and Clark (1898) reported about 6000 fur seals during investigations there late in the last century, and Lander and Kajimura (1982) indicated that the rookery at this haulout site produces about 20,000 pups each year.

St. George Island. There are six distinct haulout sites on St. George Island (Appendix 2; Kozloff 1985). A decline in the number of breeding bulls and pups similar to that recorded on St. Paul Island is also evident on St. George Island (Table 3). The most current estimates indicate that about 48,000 pups (plus at least the same number of adult females) and about 1400 harem bulls used these 6 haulout sites during 1986 (NMFS file data).

Bogoslof Island

Bogoslof Island is volcanic in origin; it rose from the sea about 65 km north of Umnak Island in the eastern Aleutians on 18 May 1796 (Orth 1967, Byrd et al. 1980; see Appendix 2). Today it is about 1.5 km long, and supports a very small number of reproductively active northern fur seals (Table 3). Nevertheless, the number of fur seals using this haulout site has grown since 1980 (Lloyd et al. 1981). The most current estimates indicate that 14 northern fur seal pups (plus the same number of adult females) and 7 harem bulls used this site during 1984 (NMFS file data) .

Northern Sea Lion (*Eumatopias jubatus* Schreber)

Background

The northern or Steller sea lion belongs to the family of eared seals (*Otariidae*). The northern sea lion is the largest of the eared seals, with some bulls exceeding 3 m in length and 1000 kg in weight. This species breeds along the west coast of North America from the southeastern Bering Sea and the

Aleutian Islands to southern California. It also breeds in Asia on the **Kurile** Islands, in the Sea of Okhotsk and on the **Kamchatka** Peninsula (Gentry and **Withrow** 1986, **Loughlin** et al. 1987; **Hoover** 1988a). Major breeding **concentrations** of this species in North America occur mainly in the northwest Gulf of **Alaska** and the Aleutian Islands; Forrester Island, off SE Alaska, is also a **major** rookery. Figure 4 shows the general distribution of this species in the eastern Bering Sea.

Similar to fur seals, the birth and the nurturing of pups and breeding by northern sea **lions** occurs on traditional, well established rookeries. As mentioned **earlier**, however, northern sea lions may haul out throughout the year (at different sites), rather than **only** during the breeding season. Nevertheless, there are definite seasonal peaks in **haulout** activity.

The annual distribution of northern sea **lions** is such that more **males** are seen along the north coast of North America during winter than during summer; individuals from California migrate northward during winter and return south in summer. Similarly, juvenile **males** from **haulout** sites in the Aleutian and **Pribilof** islands migrate north into the central and northern Bering Sea in late summer, then return south as ice begins to form.

The maximum size of the northern sea **lion** population for the 1974-1980 period was estimated to be about 290,000 individuals (some pups included); more than 196,000 (67.6%) of this total were counted in Alaska (**Loughlin et al. 1984**). The numbers of northern sea lions counted in **Alaska** during 1974-1980 apparently was unchanged **since** surveys in 1956-1960 by **Kenyon** and **Rice (1961)** and **Mathisen** and **Lopp (1963)**. However, there had been a significant shift in their distribution. Fewer sea lions were using **haulout** sites in the eastern Aleutians (**Braham et al. 1980**), and more were using **haulout** sites in the central and **western** Aleutians (**Fiscus et al. 1981**). Since 1980 there have been further significant declines in the number of northern sea lions at most **sites** in Alaska.

The area from the central Aleutian Islands (**Kiska** Island eastward) to the central Gulf of Alaska (**Sugarloaf** and Marmot islands, north of Afognak Island) has been studied more systematically than most other areas of Alaska (see

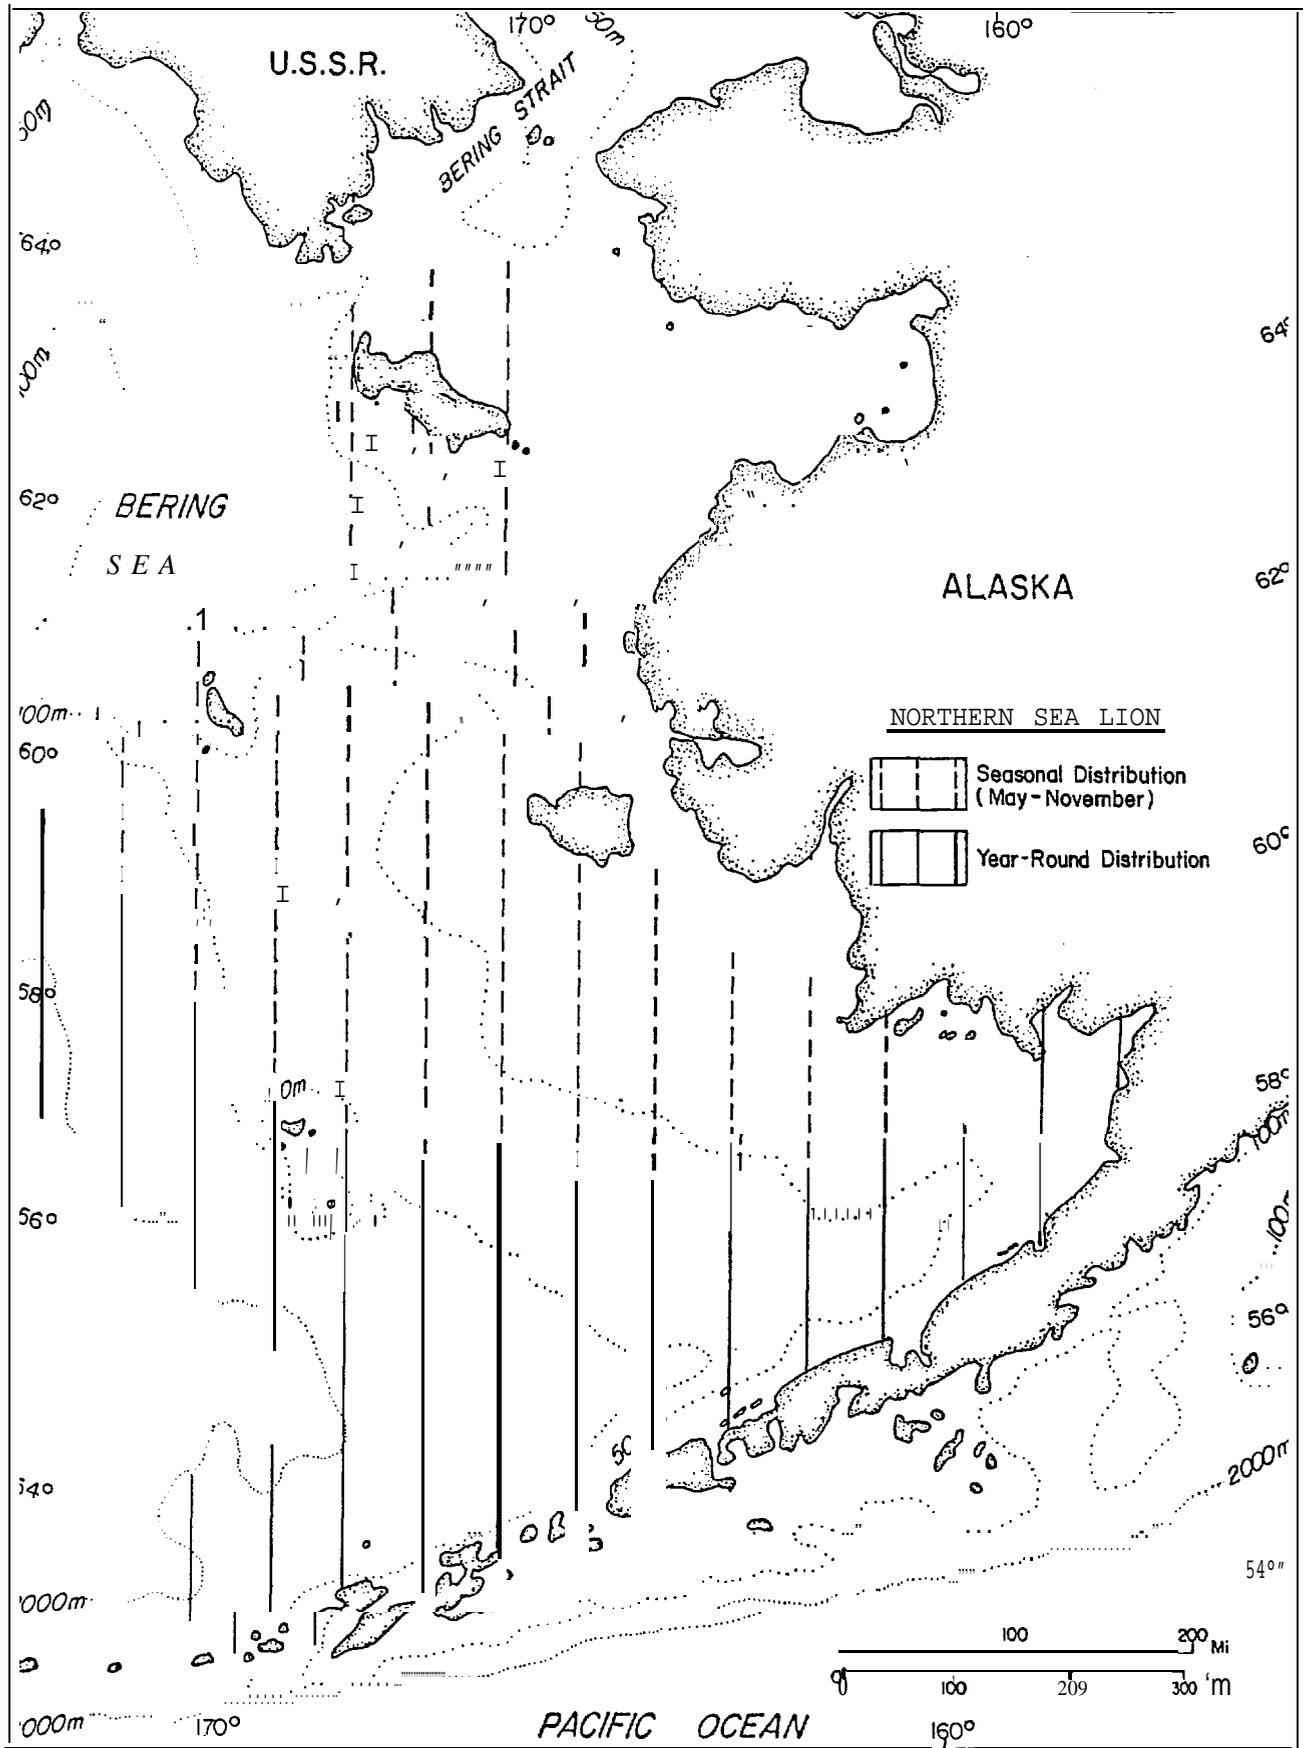

Figure 4. General distribution of the northern sea lion in the Bering Sea, Alaska.

Merrick et al. 1987), and best shows the recent declines in numbers. About 140,000 northern sea lions were counted in this area in 1958. Several different indicators confirmed that by 1985 the number had declined to less than 68,000; this represents a reduction of about 52% in 27 years or about -2.7% per yr (Merrick et al. 1987).

It is suspected that these declines may have occurred in two phases. The first decline probably was confined to the eastern Aleutian Islands and western Gulf of Alaska, and likely began in the early 1970s; it has not been possible to determine rates of decline earlier than 1969. Nevertheless, counts in the Central Aleutians to the Central Gulf of Alaska region as a whole declined by about 25% (-1.6% per yr) between 1958 and 1977 (Merrick et al. 1987). The second phase of the decline has occurred since 1977; all areas were apparently affected and the overall reduction in numbers was about 36% (-5.2% per yr) during this 8-yr period (Merrick et al. 1987). Results of counts at major haulout sites indicate that reductions may still be occurring in the southeastern Bering Sea as well as in the eastern Aleutian Islands and Gulf of Alaska.

Compared to the information available for northern sea lions in the Aleutian Islands and Gulf of Alaska, records for Bering Sea rookeries and haulout sites are less comprehensive. However, data given in Frost et al. (1983) indicate that significant declines in the numbers of northern sea lions also have occurred at Walrus Island and Dalnoi Pt. in the Pribilofs, and at Sea Lion Rock near Amak Island (North Aleutian Shelf).

The ultimate causes of the decline in the northern sea lion population in Alaska are unknown (Merrick et al. 1987). However, it has been postulated that disease (possibly Leptospira), changes in prey resources, mortality through shooting, and possible entanglement in nets and other debris may all be contributing factors. Some evidence suggests that changes in the quantity and size of walleye pollock (Theragra chalcogramma), the principal prey of northern sea lions, may be a significant factor in the decline (Frost and Lowry 1986, Loughlin 1987, Bakkala et al. 1987).

Patterns of Occupancy at Haulout Sites

Northern sea lions occupy haulout sites at different times depending on their sex and age. In general, the oldest and strongest bulls return to rookeries first, followed by adult females. The first bulls begin arriving at Aleutian Island rookeries in mid-May. They usually begin to abandon their territories in mid-July and move to nearby hauling grounds by mid-August (Table 4). Some pregnant females also begin arriving at rookeries in mid-May; pupping usually occurs within 2-3 days of arrival. Although pups are born at Alaskan rookeries from mid-May through mid-July, the peak of pupping is during the 10-20 June period (Calkins 1985).

Table 4. A summary of the occupancy of haulout sites on the Eastern Aleutian Islands and SE Bering Sea, Alaska, by different age and sex classes of northern sea lions.

Pups		1 ————— 3 ————— ..						

* '1' in the time line indicates the approximate dates of arrival at rookeries, '2' indicates the approximate date of abandonment of territories by adult bulls and breakdown of the social structure of the rookery, and '3' indicates the beginning of the departure of sea lions from their haulout sites in the study area.

Pups begin nursing almost immediately after birth, and are nursed until the female breeds again, usually within two weeks of pupping. Females stay ashore with their pups for an average of 6.7 days (\pm 2 days) before making their first feeding trip to the sea (Higgins et al. 1988). This is the first period of feeding by females after they arrive at the rookery. They assume a schedule of feeding at night and suckling their young during the day. At about 14 days of age pups first enter the sea; for about two weeks they restrict

their swimming activity to littoral zone pools (Sandegren 1970). Each day they spend more time in the water, and eventually join their mothers on 'tours' of deeper waters adjacent to the rookery. Pups are usually able to swim and dive quite well after about 28 days in pelagic waters with their mothers.

The number of sea lions at rookeries during the breeding season show diel fluctuations, with early morning lows and late afternoon highs resulting from the movement of females to and from the sea to feed (*mostly* nocturnally). The numbers of sea lions in some locations are also affected by tide and weather (Sandegren 1970; Withrow 1982). Calkins (1985) indicated that the areas over which sea lions forage are very broad, extending from the intertidal zone to the continental shelf break.

Males leave the rookeries immediately after the breeding aggregation breaks down in mid-July to August. Most adult females and young have left their rookeries by mid October, **However**, in the eastern Aleutian Islands the majority of the breeding population is **still** present at **haulout** sites through the end of October. As mentioned **above**, there is a general northward movement of sea lions (primarily immature **bulls**) into the central and northern Bering Sea. They usually occur in largest numbers on **St. Lawrence Island (63°30'N)** **during** September. In the central **Bering Sea region**, sea lions **also** may haul out on sea **ice** when **it is** present **during** winter and **spring**.

Location and Status of Northern Sea Lion Haulout Sites

There are approximately **15** rookeries and associated hauling grounds used by large numbers of northern sea lions in the eastern Bering Sea, and there are about **30** additional sites where smaller numbers have hauled out (Table 5; **Fig. 5**; Appendix 3). Only six of the total number of **haulout** sites are rookeries where more than one or two pups are **born**, and all but one of these sites are in the eastern Aleutian Islands or extreme southwestern part of Bristol Bay. The exception is Walrus Island, in the **Pribilof** Islands group (**Table 5**). Similar to the situation described for the northern fur seal (Lloyd et al. 1981), the locations of key northern sea lion **haulout** sites, especially the rookeries, may in part be determined by important oceanographic features

Table 5. Peak counts of northern sea lions at major haulout sites in the Bering Sea, Alaska.†

† Note: data in this table are from many different sources and years; they have not been collected systematically or consistently. Peak counts at different sites on the same island may be from different censuses; only counts of adults/subadults and pups at a rookery may be from the same census and may be summed. Unless otherwise indicated, counts are of adults/subadults.

Peak count data were taken from Kenyon and Rice (1961), Kenyon (1962;1965), Mathisen and Lopp (1963), Brahm et al. (1930), Frost et al. (1983), Loughlin et al. (1984), Calkins (1985), Merrick et al. (1987), O'Neil and Haggblom (1987), Sherburne and Lipchak (1987), EnviroSphere Co. file data, NMFS file data, USFWS file data, ADFG file data.

* Signifies that this haulout site is (or has been) a major rookery (breeding area) where a significant number of pups are (were) born. The Ugamak I. group includes Round L.

"--" signifies that no data are available.

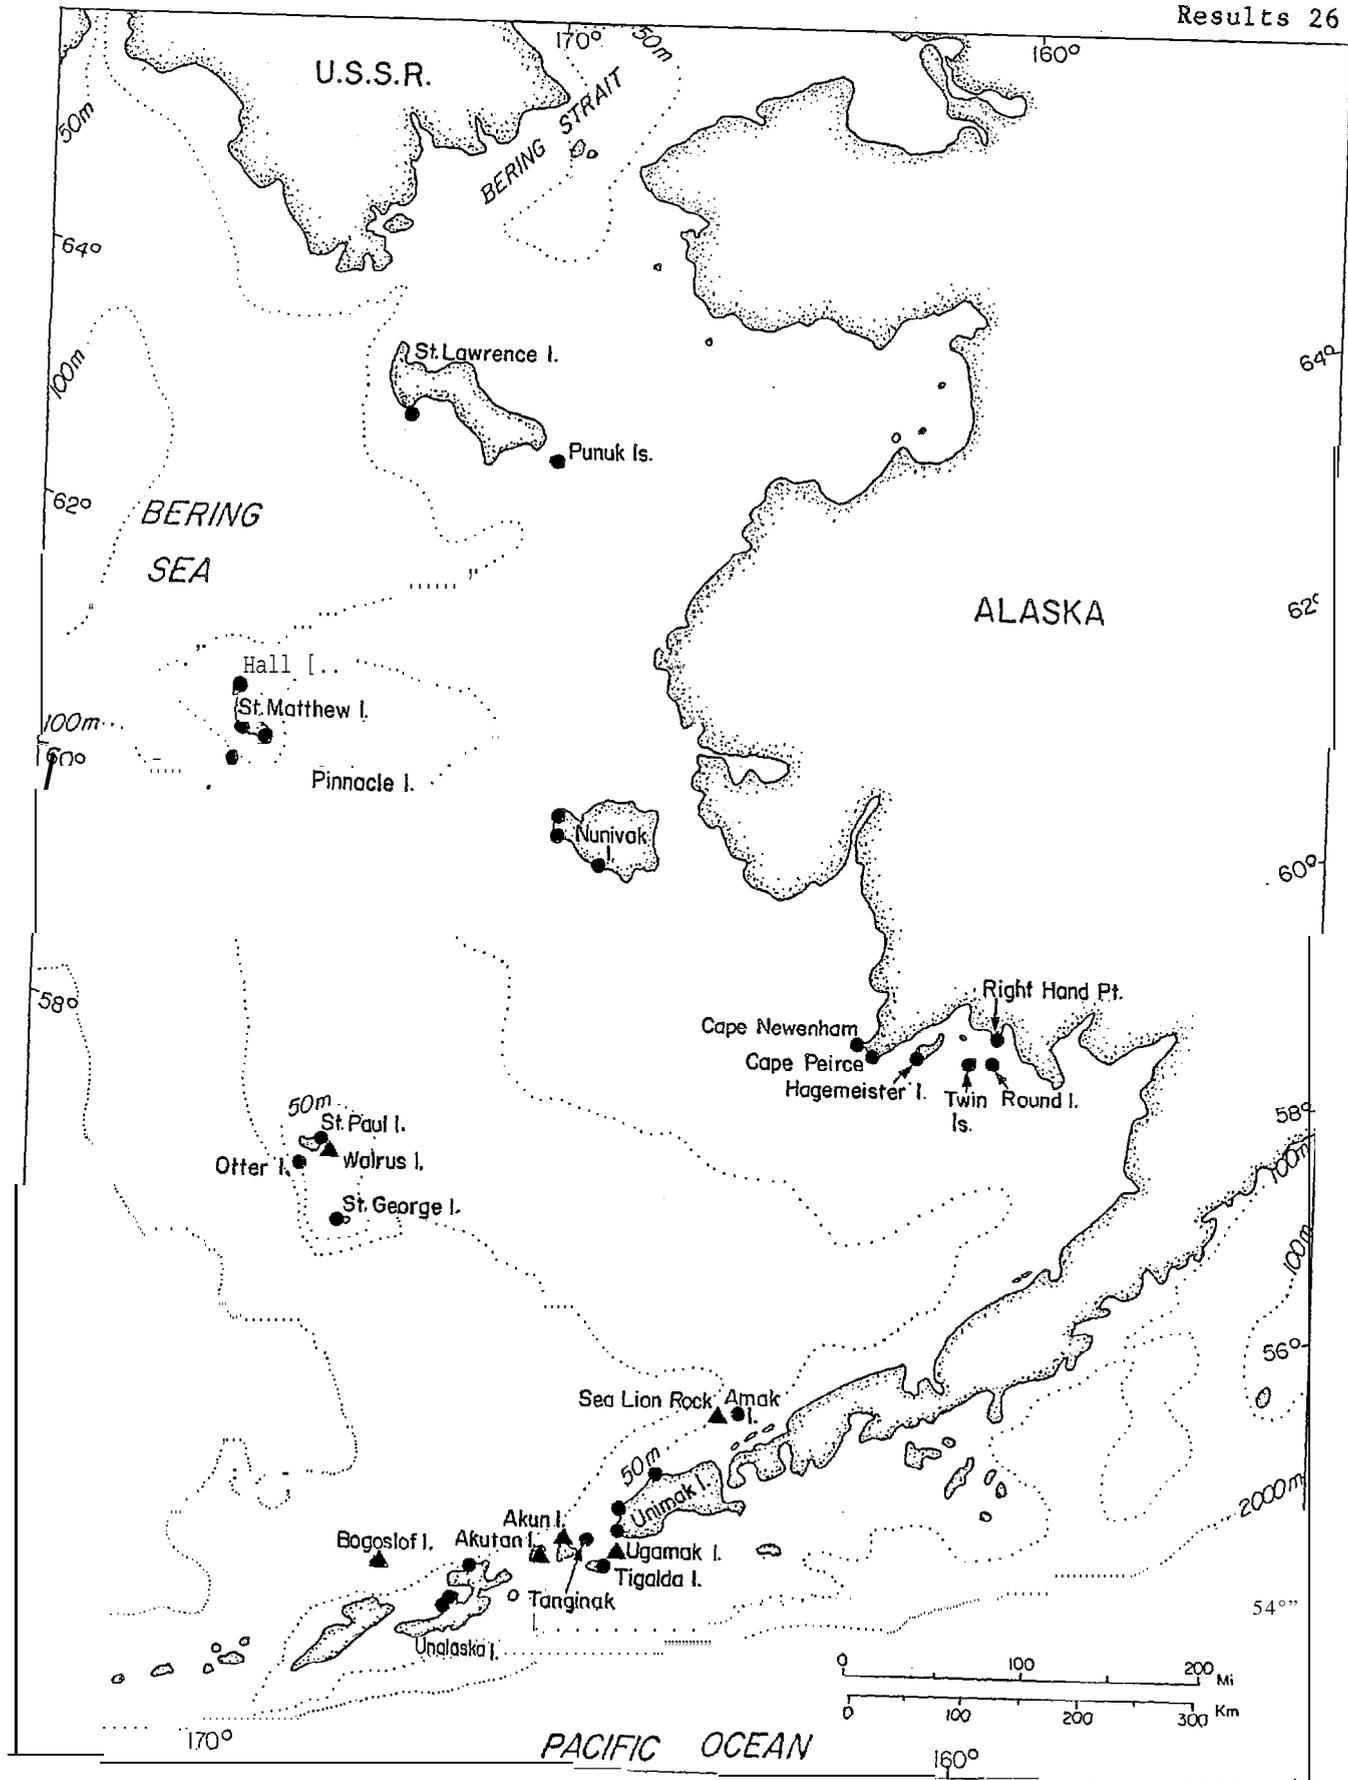

Figure 5. Locations of important haulout sites used by northern sea lions in the Bering Sea, Alaska. Sites designated by (A) are rookeries.

which effect the distribution and abundance of principal prey (see earlier discussion of northern fur seal).

Sea lions occur irregularly and in small numbers (usually as singles) along the mainland coast of Alaska north of Cape Newenham; there are no known rookeries or **haulouts** used on a regular basis in this area. General comments of long-time residents indicate that single animals are known to have occurred on **Besboro** Island, Cape Denbigh, Cape **Darby**, Rocky Point, Cape Nome, Sledge Island and Cape Prince of Wales. During summer and autumn Nunivak Island is also regularly visited by relatively small numbers of northern sea lions, most of which are presumed to be -juvenile males. The largest number that has been reported at any of these sites was 50 (Frost et al. 1983; Table 6.9). Lantis (in Kenyon and Rice 1961) indicated that sea lions were familiar to **all** of the Nunivak Island hunters, though they were not considered by them to be numerous. The sites near Cape **Mendenhall** and Cape Mohican are used most frequently (E. Shavings, pers. comm.).

At St. Lawrence Island, sea lions usually occur in small numbers (1-6 animals) in the autumn (**Kenyon** and Rice 1961). Reportedly sea lions are molting when they haul out on St. Lawrence Island. The two main **haulout** locations are at Southwest Cape and on South **Punuk** Island (**F.H.** Fay in Kenyon and Rice 1961). In one exceptional case, on 25 September 1953, Fay recorded about 1000 northern sea lions hauled out on the rocks and beach at Southwest Cape; three or four days later there were **about** 200 animals hauled out on South **Punuk** Island. Aside from this report, there have been no other sightings of more than 100 animals at **haulouts** in the St. Lawrence Island area. Farther north, at King and Little Diomedé islands, sea lions occur irregularly, mostly as single animals during late summer and autumn.

Harbor Seal (*Phoca vitulina* L.)

Background

The harbor seal belongs to the family of true or earless seals (**Phocidae**). The distribution of the Pacific form (*Phoca vitulina richardsi*) extends as far south as the coast of Baja California and north to the Gulf of

Alaska, along the entire Aleutian Islands, and into **the** Bering Sea (Jeffries and Newby 1986; Hoover 1988b). Harbor seals are regularly found as far north in the Bering Sea as the **Kuskokwim** River mouth and **Nunivak** Island, and as far offshore as the **Pribilof** Islands where they are year-round residents (Frost et al. 1983). On **the** other hand, large-scale seasonal movements apparently occur in **Kuskokwim** Bay and northern Bristol Bay where many harbor seals are found in summer but few are found in winter when the area is largely covered with ice (Pitcher 1980; J.J. Burns, pers. comm. 1988). In general, the harbor seal is replaced north of **Nunivak** Island by the ice-breeding spotted seal (**Phoca largha**), whose pups are born much earlier and with white coats. Figure 6 shows the general distribution of the harbor seal in the eastern Beaufort Sea.

An interesting situation exists in the **Pribilof** Islands area where harbor seals occur in small numbers in all areas (especially when compared with the northern fur seals) except on **Otter** Island. Johnson (1974) estimated that about 1300 harbor seals were hauled out on Otter Island in 1974; Fiscus (cited in Johnson 1974) estimated that there were about 1500 harbor seals throughout the **Pribilof** Islands area. It should also be noted that the ice-associated spotted seal (**Phoca largha**) is abundant on the pack ice in heavy ice years when it extends as far south as the **Pribilof** Islands; a few of these seals, mainly pups, occasionally come ashore.

Harbor seals are more-or-less restricted to the coastal zone. Although they do not undertake regular seasonal migrations on a large scale, they are known to move considerable distances. One radio-tagged individual crossed a 75 km stretch of open water between two islands in the Gulf of Alaska. Other individuals have been seen up to 80 km from shore. Tagging studies have shown that young harbor seals move up to 250 km from their place of birth (Pitcher 1980). During the 1960's when the seals (primarily pups) were killed for the fur trade, hunters active at haulout sites on the Alaska Peninsula recognized that seals harassed and displaced from one site would move to another (e.g., from Port Heiden to the Seal Islands). Also, some harbor seals move northward along the Alaska mainland during summer and early autumn.

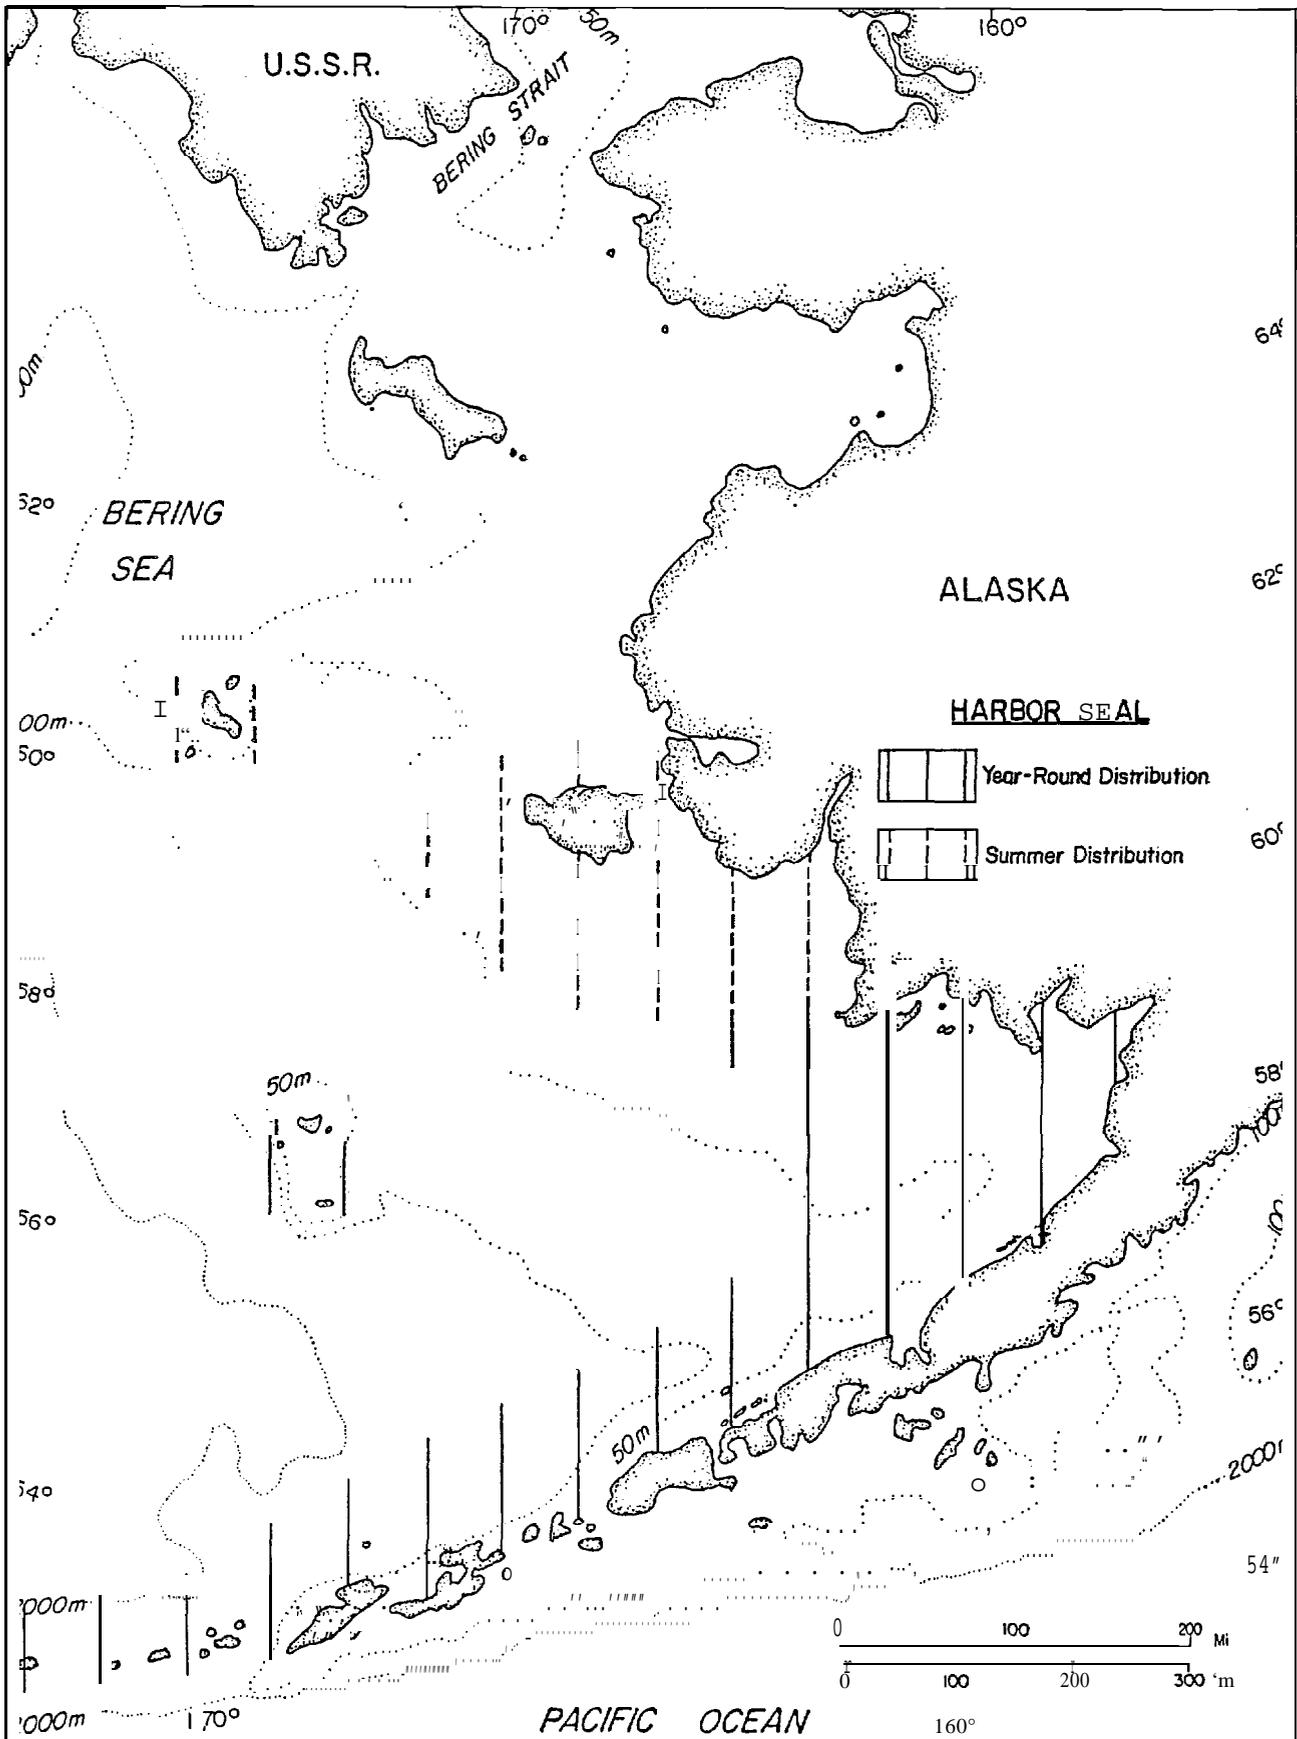

Figure 6. General distribution of the harbor seal in the Bering Sea, Alaska.

In general, most harbor **seals** haul out of the water to **rest**, give birth, and suckle their pups. However, **it** is not necessary for them to be hauled out to give birth; occasionally a pup is born and suckled in the water (J.J. Burns, **pers. comm.** 1988). Sand and **gravel** beaches, sand and mud bars, reefs, **low lying** rocks and ledges and pieces of ice are used as **haulout** areas. **It** is probably important for harbor **seals** to haul out during the molt period. The peak of the adult molt period on **Otter** Island (in the **Pribilof** Islands) was in late August (Johnson 1974); this period is probably the same throughout most of the Bering Sea. Access to food, freedom from disturbance, ready access to **water**, and protection from wind and wave action are among important criteria for **haulout site** selection by harbor seals.

Harbor seals reach sexual maturity at about 6 years of age, and may live for 30 years (**Jeffries** and Newby 1986; Hoover 1988b). In the Bering Sea **mating** takes **place** (in the water) mainly from mid-July to early August. As with other **phocids**, there is a period of arrested embryonic growth and **delayed** implantation with implantation occurring in late October to early November (Burns and **Gol'tsev** 1984). Most pups are born during the **early** June to **mid-July** period. As a **rule**, pups are born on land. They enter the water shortly after **birth**, as most preferred **haulout sites** in the study area are awash **during** the **twice-daily high tides**. According to Lawson and **Renouf** (1987), prior to weaning, pups spend as much time in the water as out of it. They also found that the highly defensive behavior of mothers, together with the maternal bonding immediately after birth (especially during the first five minutes after **birth**), was responsible for maintaining early mother-pup contact. After that short time, pups followed their mothers. Mother-pup pairs went into the water about 50 minutes after birth. Some pups apparently remain with their mothers after weaning. In areas such as estuaries, where **haulout habitat is limited**, they may **segregate** into nursery groups composed almost exclusively of females with pups.

The population of harbor **seals** along the Pacific coast of North America is composed of about 330,000 individuals, of which almost 80%, or 260,000 individuals are found in Alaska (**Jeffries** and Newby 1986). The size of the eastern Bering Sea population was conservatively estimated to be about 30,000 in 1973. However, it was estimated that about 29,000 were present on sand and

mud bars in the large estuaries on the north side of the Alaska Peninsula (Izembek Lagoon, Port Moller, Seal Islands, Cinder River, Port Heiden and Ugashik Bay) during the period 1975-1977 (Everitt and Braham 1980). Thus the overall estimate for the Bering Sea may have been in excess of 30,000. Harbor seals are difficult to census since the only time when they can be counted with any degree of accuracy is when they are hauled out. Although they haul out by the thousands in some locations, the proportion of the total population that may be hauled out at any one time is unknown, thus repeated counts usually represent trends in abundance rather than precise censuses.

Harbor seals and spotted seals reach the greatest degree of sympatry in the coastal zone from northern Bristol Bay (Nanvak Bay) to Kuskokwim Bay. Spotted seals occur in greatest numbers when the seasonal sea ice is present. Thus they move farthest south in greatest numbers during late winter and spring, although some occur in the coastal zone during summer and autumn; their abundance in this area increases from south to north. Arvey (1973) initiated a field study of sympatry in these seals and found that in summer, a small proportion of the seals hauled out in Nanvak Bay were spotted seals; the majority were harbor seals. Based on seals killed by subsistence hunters in Kuskokwim Bay during May and July, Arvey also found that one species replaced the other as the season progressed. All of the seals he examined in May were spotted seals, whereas those taken in July were harbor seals. The relative abundance of seals also showed a seasonal trend; seals were very abundant in May through early June and were much less abundant by July. These findings suggest that in the northern part of their range harbor seals are probably migratory; they occupy northern coastal areas in summer that are vacated by spotted seals in late spring after the ice disappears.

Harbor and spotted seals are also sympatric on coastal areas of the mainland from northern Bristol Bay northward, and around the central and northern Bering Sea islands. The actual number of harbor seals in this area is small and there are no known major haulout sites (i.e., where more than 100 have been reported to haul out). Nunivak Island seems to support the greatest number, and they may occur there year-round; the largest numbers of harbor seals recorded on Nunivak Island are at Ikookstakswak Cove, 5 km NE of Cape Mohican, at the west end of the island (<45 seals), in the bays around Ikook

Point at the extreme western end of the island (up to 70), and in the vicinity of Cape **Mendenhall** on the southern tip of the **island** (up to 80). They are present on islands of the St. Matthew group, though in small numbers, and they probably occur infrequently in the **St. Lawrence Island** area.

Burns (J.J. Burns and ??, **H. Fay**, unpubl. data) was able to confirm the presence of harbor seals on St. Matthew **Island** based on definitive photographs taken by **R. Johnson** (Univ. of Alaska) on 20 August 1986. However, spotted seals are more abundant and they haul out in relatively large numbers (more than 100 in a herd) at several locations in this island **group**, as suggested in Frost et al. (1983). According to **L.F. Lowry** (ADFG, Fairbanks, AK) **only** the spotted seal was seen during observations on St. Matthew **Island** in mid-June 1986 when sea ice was still present. Few **harbor seal** pups are born on **St. Matthew Island** and **St. Lawrence Island**, and the few that **biologists** and native hunters have reported there are probably **only** seasonal residents during late summer through early autumn.

Records of harbor **seals** north of Kuskokwim **Bay** are particularly poor, although they are known to coastal residents as far north as **St. Michael**, on the southern shore of Norton Sound. They are usually referred to as "summer" seals or freshwater seals.

Patterns of Occupancy at **Haulout Sites**

Pitcher (1980) mentioned that studies in Washington State and San Francisco Bay have shown that harbor seals may adapt the timing of **haulout** to avoid human disturbance in some situations. Autumn **haulout** patterns by harbor **seals** on San Miguel Island, California, indicated that the largest proportion of individuals under observation hauled out between 13:00 and 15:00 h (Yochem et al. 1987). Most seals remained hauled out less than 12 h, and most seals were hauled out on fewer than 51% of the days sampled. Only about 40% of a sample of tagged **seals** hauled out each day; only 19% of tagged **seals** were hauled out during peak afternoon hours.

Renouf et al. (1981) found no recognizable diurnal pattern to harbor seal movements where harbor seals hauled out in a shallow bay on the French island of **Michelon**, in the Gulf of Saint Lawrence, Canada. They also found no relationship between **the** direction and intensity of seal traffic and various weather factors.

Johnson (1974, 1977) found more harbor seals hauled out on Otter Island, Alaska during his morning census (09:00 h) than during his evening census (21:00 h). In the southeastern Bering Sea, on the other hand, Everitt and **Braham (1980:285)** found a strong inverse correlation between the number of harbor seals hauled out and tide level. Significantly more seals were seen at lower tides than higher tides, regardless of whether the tides were rising or falling. This relationship has also been reported elsewhere (Scheffer and **Slipp** 1944, Fisher 1952, Bishop 1967, Newby 1971; all seen in Everitt and **Braham 1980**).

Repeat counts of harbor seals hauled out at Port Heiden in 1971 (data from Pitcher, in Frost et al. 1983; and Pitcher 1986) and on Otter Island in 1974 (data from Johnson 1974) illustrate the magnitude of day-to-day and week-to-week fluctuations in the number of individuals recorded at **haulout** sites (Fig. 7).

Location and Status of Harbor Seal **Haulout** Sites

Unlike the situation described for the northern fur seal and northern sea lion, births of harbor seal pups apparently are not restricted to a select few rookeries. As indicated by their broad distribution and occupation of habitats with many different physical characteristics, harbor seals are quite adaptable. It is thought that areas with adequate prey, especially in large expanses of shallow water, are necessary to support large harbor seal populations.

The number of harbor seals recorded at haulout sites in the Bering Sea, especially at some sites in the southeastern Bering Sea, has apparently declined dramatically during the recent decade (Pitcher 1986). Numbers of harbor seals may have been below carrying capacity during the early to mid

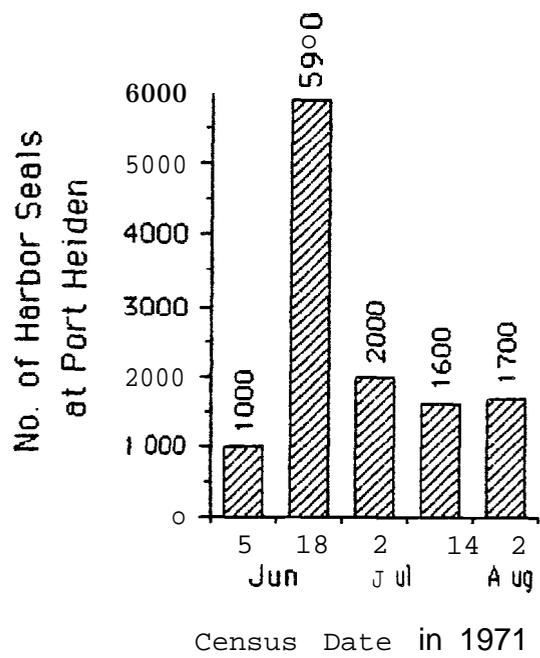

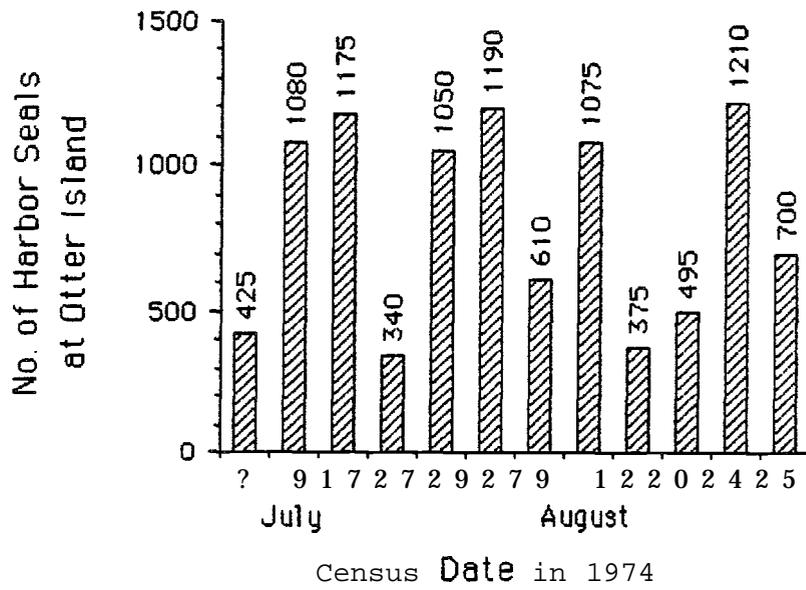

Figure 7. Variability in counts of harbor seals at two haulout sites in the Bering Sea, Alaska. Otter Island data are from Johnson (1974); Port Heiden data are from Pitcher (1986, in Frost et al. 1983).

1960's when as many as 50,000 individuals were harvested in Alaska in 1965 (Pitcher 1980). The harvest declined until the early 1970's when the Marine Mammal Protection Act of 1972 (MMPA) was passed. **Currently**, most of the harvest is taken by Alaskan Natives under the Native Exemption to the MMPA. Although several reasons have been given for the apparent recent decline of harbor seals (e.g., disease, over-exploitation in earlier years, increased predation, increased fouling in fishing gear, supposed reductions in principal prey [walleye pollock]), none of these suggestions have been clearly documented.

We have identified about **33 haulout** sites that are or have been important for harbor seals in the Bering Sea and 9 other sites for which there is less complete information (Table 6; Fig. 8; Appendix 4). Except for the recent counts at several major **haulout** sites along the north side of the Alaska Peninsula, there is little current published information for several sites that were last **censused** and considered to be important in the 1970's. In general, the largest proportion of harbor seals in the Bering Sea occur along the north side of the Alaska Peninsula and in Bristol Bay (25,000-29,000), in Nanvak Bay (3,000), and at Otter Island (1,300; see Table 6). Smaller numbers are scattered along the coast of the Bering Sea, but no other major concentration areas have been recorded.

Walrus (*Odobenus rosmarus* (L.))

Background

The Walrus shares some characteristics with both the **otariid** or eared seals (fur seals and sea lions) and the **phocids** or earless seals (harbor seal, spotted seal, ringed seal and relatives). However, because of several distinct characteristics, such as its skin, method of sleeping at sea and feeding, and its distinctive tusks, it is placed in a separate **taxonomic** family--*Odobenidae* (Kenyon 1986). The walrus is among the largest of pinnipeds, with some males weighing almost 1600 kg; only the elephant seal (*Mirounga angustirostris*) is larger. The species has a discontinuous **holarctic** distribution; the widest gap is between the eastern **Chukchi** Sea and the central Canadian Arctic (Fay 1985). The range of the Pacific Walrus (*Odobenus rosmarus divergens*) is generally

† Note data in this table are from many different sources and years and have not been collected in a systematic or consistent fashion. Sources of peak count data are Kenyon (1960, 1965; Mathisen and Lopp (1963); Johnson (1977); Everitt and Braham (1979, 1980); Frost et al. (1983); Pitcher ~1986) NMFS file data; USFWS file data; J. J. Burns field notes.

* The Nanvak Bay haulout site is reported to be the most northerly pupping colony of harbor seals in the Bering Sea (Clarence Rhode Nat. Wildl. Refuge Rep. 1981, in Frost et al. 1983).

** Adult harbor seals, many with pups, were seen on sandbars at the mouth of the Kuskokwim River on 4 July 1972 (R. Baxter pers. comm., in Frost et al. 1983). Hence, haulout sites in Kuskokwim Bay, rather than Nanvak Bay, actually may be the most northerly pupping colony of harbor seals in the Bering Sea.

-- signifies that no data are available.

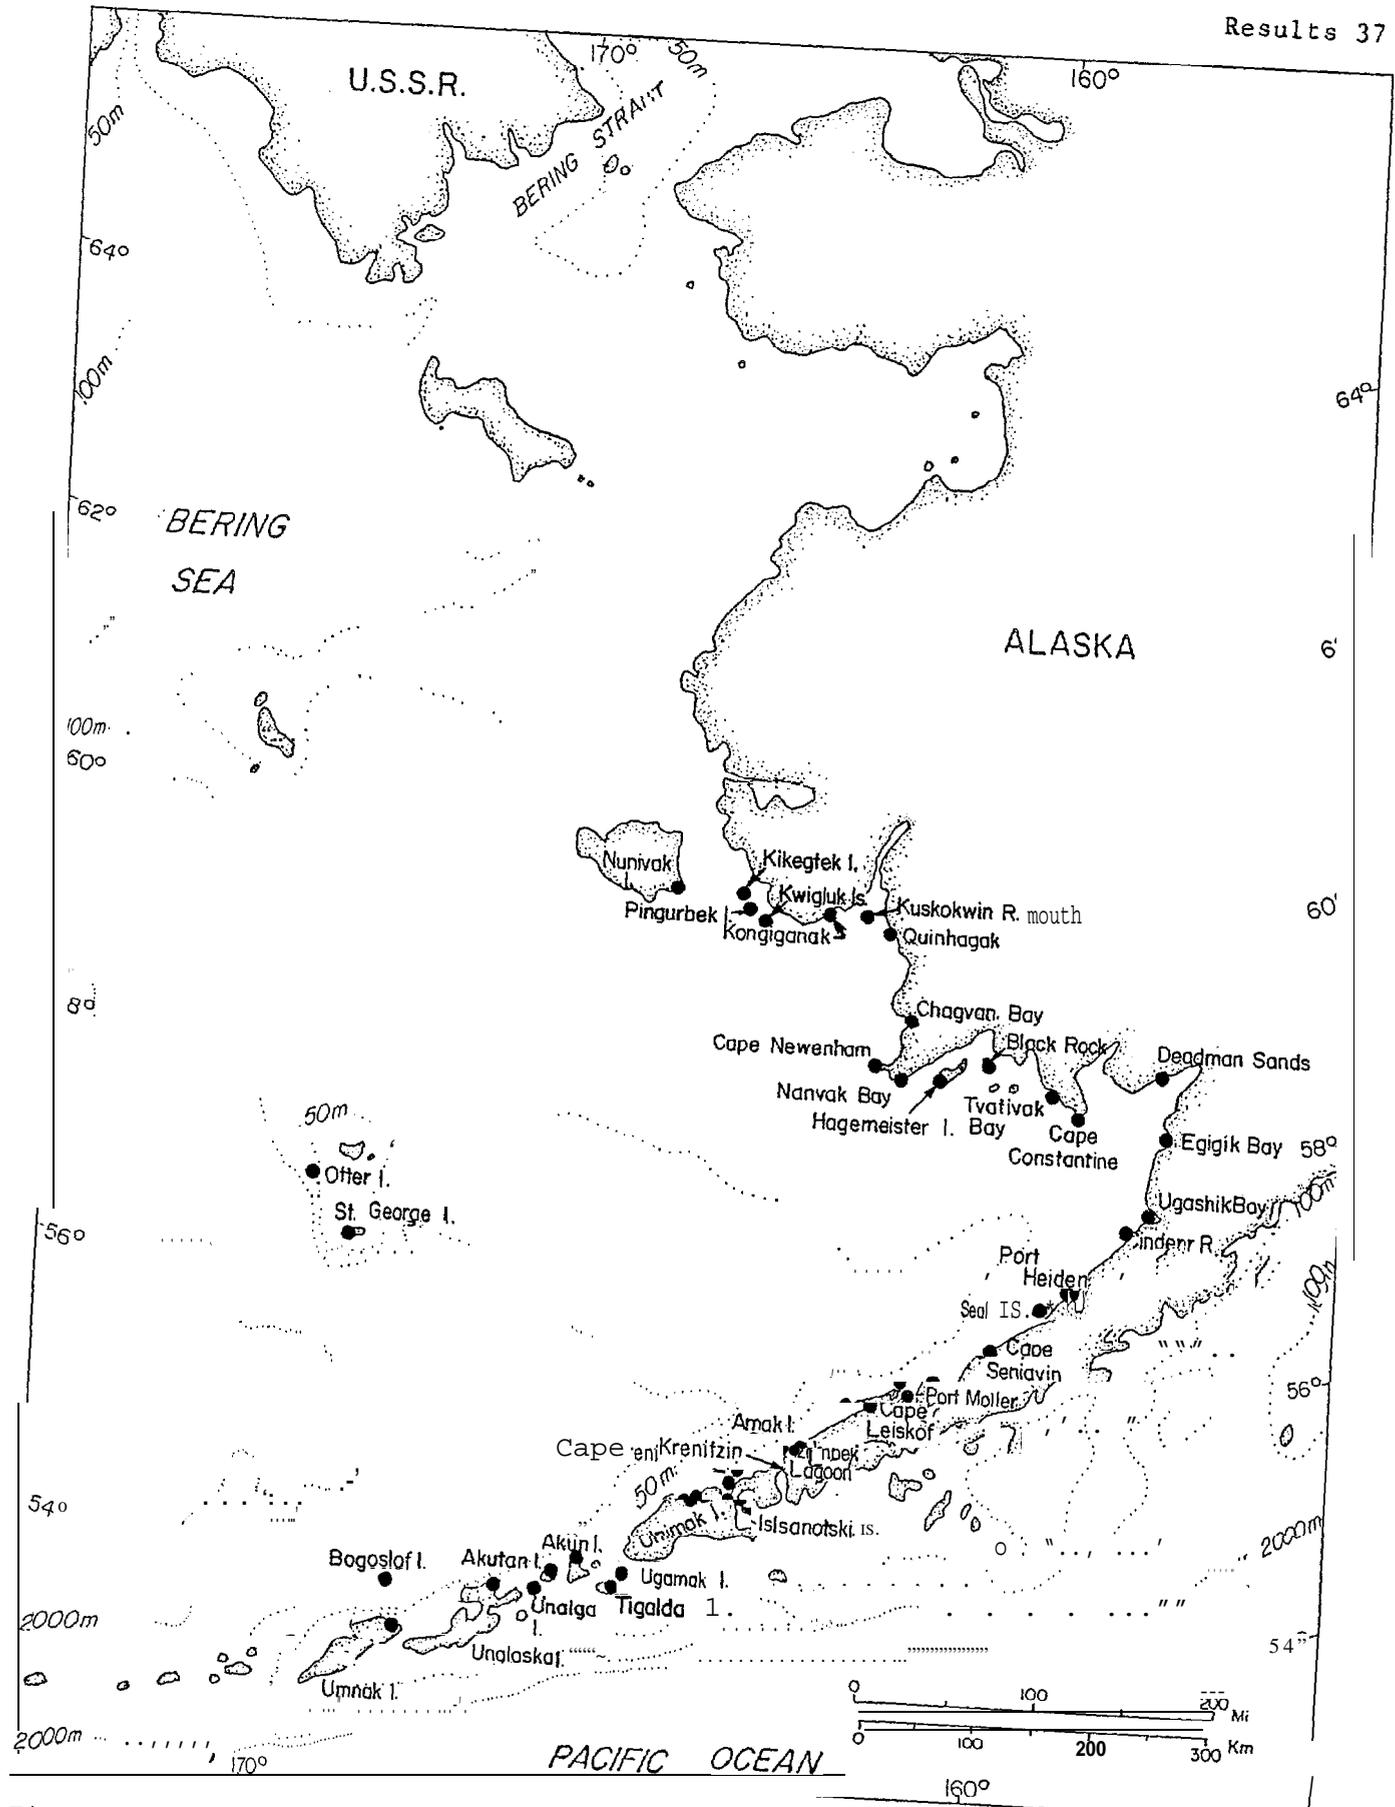

Figure 8. Locations of important haulout sites used by harbor seals in the Bering Sea, Alaska.

confined to the Bering **and Chukchi** seas. Aerial surveys conducted during 1960-1972 showed that when the Bering Sea ice pack is at its maximum, walrus though widely distributed were concentrated in two principal locations in **the** Bering Sea: north and south of **St.** Lawrence Island, and **in** southeastern Bristol Bay (**Kenyon** 1986; Sease and Chapman 1988). Figure 9 shows **the** general annual distribution of the species **in** the eastern Bering **Sea**.

Male walrus reach sexual maturity at 8-10 years but do not reach physical maturity (i.e. are not able to successfully compete for mates) **until** about 15 years of **age**. Females reach sexual maturity at about 6-8 years of age and may give birth **to** a single calf about every 2 years. **Calves** are born on the ice in April or May after a gestation period of **14-15** months. Walrus may **live** to be 35-40 years of age (Fay 1985).

Walrus feed primarily on bivalve **molluscs** which **they** obtain from bottom sediments in the shallow continental shelf waters of the Bering and **Chukchi** seas (Fay 1985, Nelson and Johnson 1987). The distribution and abundance of the **walrus** is thought to be closely tied to the availability of **large** volumes of **molluscan** crustaceans; captive walrus consume **up to almost** 30 kg of bivalves daily (Kenyon 1986).

The size of the Pacific walrus population was greatly reduced during the **last** half of the 19th century and again during the 1950's. The first of those major reductions "resulted in the virtual extirpation of walrus from **haulout** sites **in** southeastern Bering Sea and the **Pribilof** Islands. Elliot (1882) indicated that walrus had formerly hauled out on the **Pribilofs in** large numbers, and he referred to the acquisition of considerable amounts of ivory from there (**by** early Russian hunters and traders) as proof of the former abundance. **Jordon** and Clark (1898) considered that walrus were practically extinct on the **Pribilofs** and True (1899) said that they had been exterminated there.

Pacific walrus have increased greatly since the 1950's; the population was estimated to be 250,000 animals in 1980 (Fay et **al.** 1984; Sease and Chapman 1988) and many experts believed that the walrus population had reached or exceeded the long-term carrying capacity of the habitat. The increase

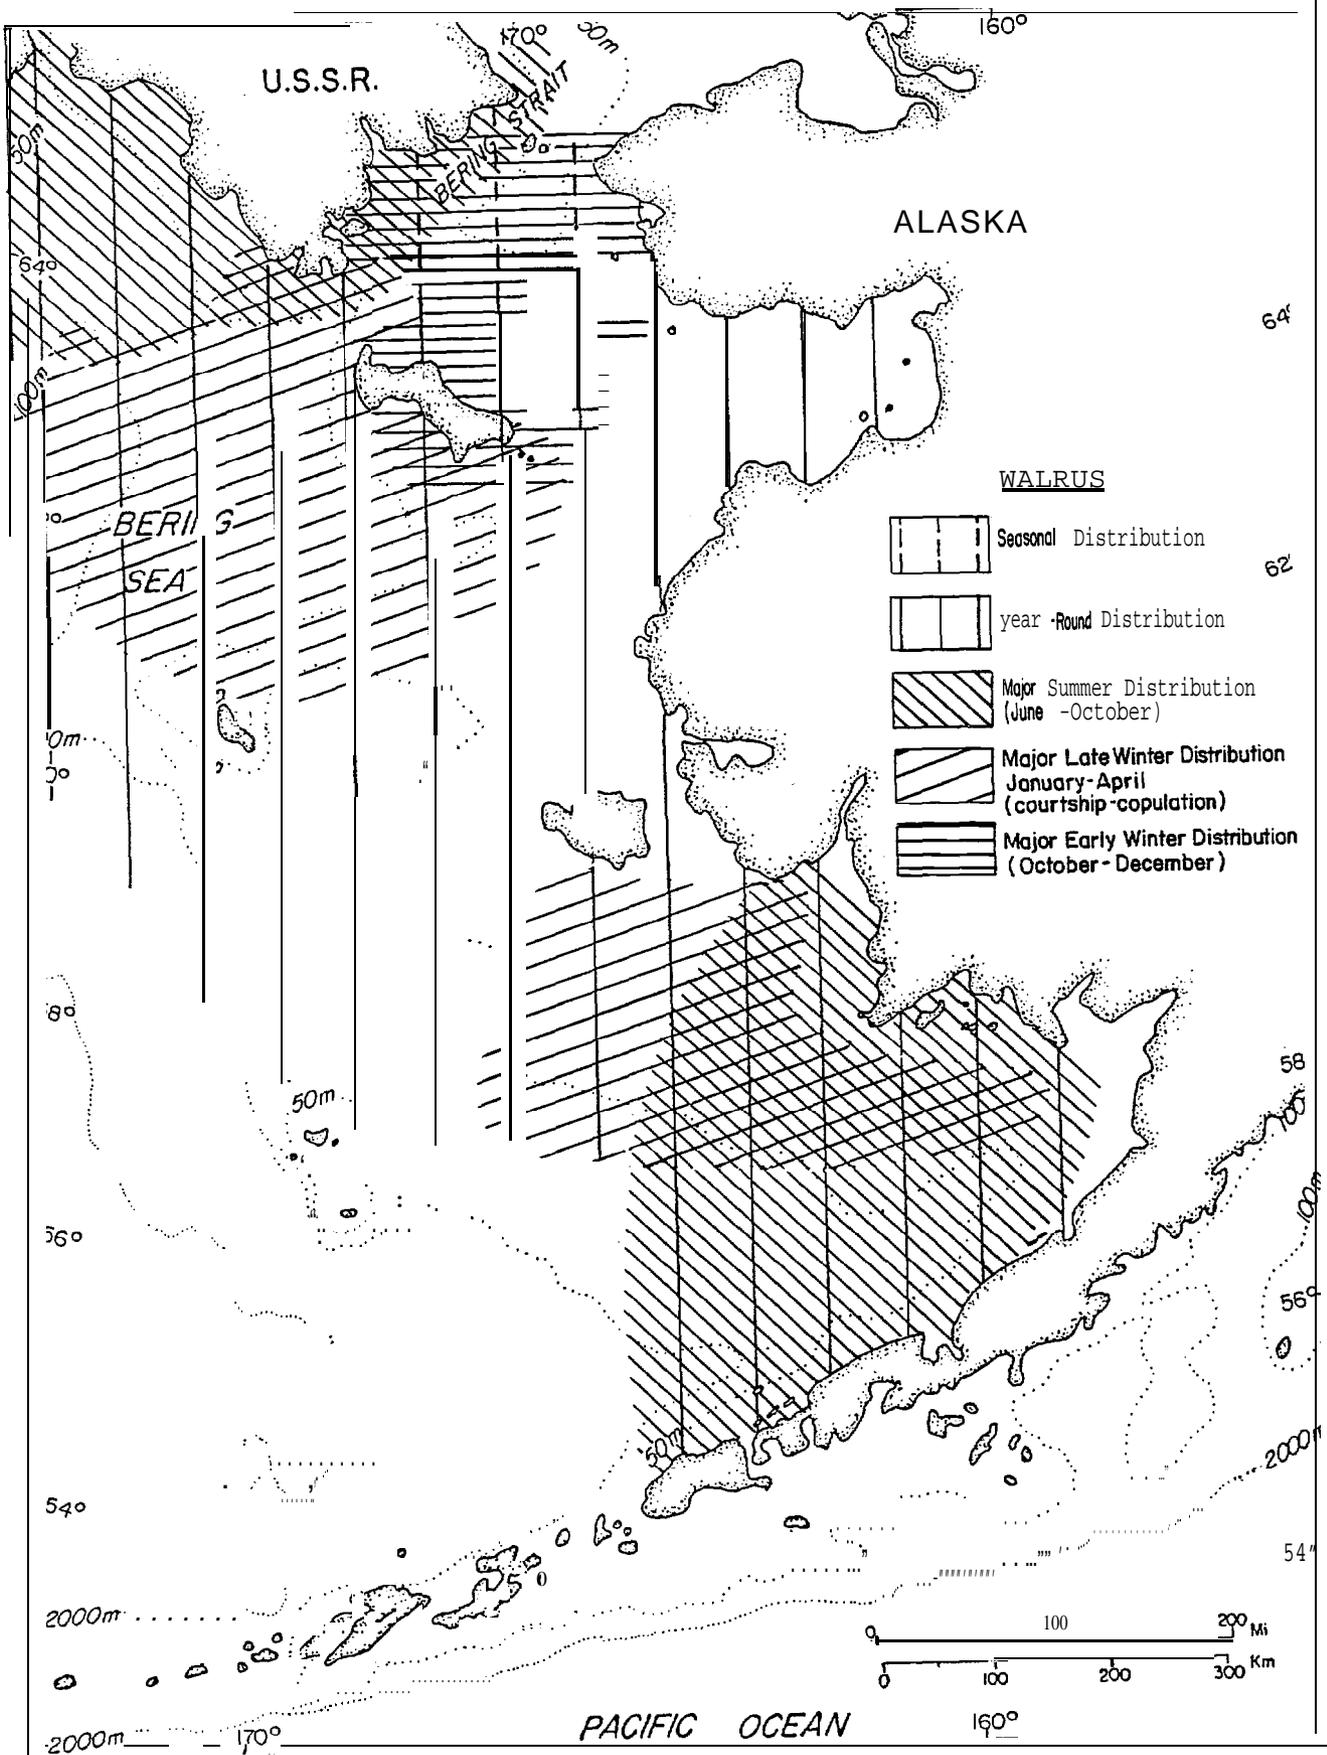

Figure 9. General distribution of the Pacific Walrus in the Bering Sea, Alaska.

resulted **in** the reoccupation of many former hauling grounds; so far, **however**, the **Pribilof** Islands remain a notable exception.

Patterns of Occupancy at Haulout Sites

The distribution of Pacific walrus **varies** considerably throughout the year. Males and females aggregate together **in** the pack ice as far north as St. Lawrence Island during late **winter** and early spring, **which is** when **mating** occurs; during some **mild** winters, many walrus may **remain in the** northern **Bering** Sea throughout the winter. **As** the **ice** pack breaks up and begins to move north (May-July), the population **of** walrus segregates; females with young stay with the ice and drift north through the Bering Strait into the **Chukchi** Sea. Virtually all males move toward the coast and south **into** Bristol Bay where they aggregate in large numbers at traditional **haulout** locations, principally **along** the north coast of Bristol Bay (**Kenyon 1986; Sease and Chapman 1988**). The largest and most regularly used summer **haulout** sites for these **bull** walrus are on the Walrus Islands (Round Island, N. Twin Island, High Island) and at nearby Cape Peirce (Fig. 10).

Bulls remain at these coastal **haulout** locations throughout the **summer-**early fall period, after **which** they **begin moving** west and north to rendezvous **with** the females and young that have drifted south with the advancing pack ice. Large numbers of walrus sometimes aggregate on **St. Lawrence Island** and regularly on the nearby **Punuk** Islands during October through December.

Walrus are known to be synchronous in their arrival **at** and departure from **haulout** sites on land and ice (**Mazzone 1987; O'Neil and Haggblom 1987**). To date that phenomenon, **although** important to the issue of protecting **haulout** sites, has not been adequately studied. **All** observations at **haulout** sites on **land** show generally alternate peaks of high and low numbers. At Cape **Peirce**, **Mazzone** (1987) reported that during the summer of 1985 and 1986 walrus were ashore for an average of 2,54 days and were away (presumably at sea) for an average of 8.5 days. **O'Neil and Haggblom** (1987) found that the mean duration of time ashore at Cape Peirce was 2.97 days and the time away from the **haulout** sites was 7.87 days. Counts of walrus hauled out at Cape Seniavin in 1987 and 1988 (data from S. Hills, **USFWS** pers. **comm.** 1988) illustrate the magnitude

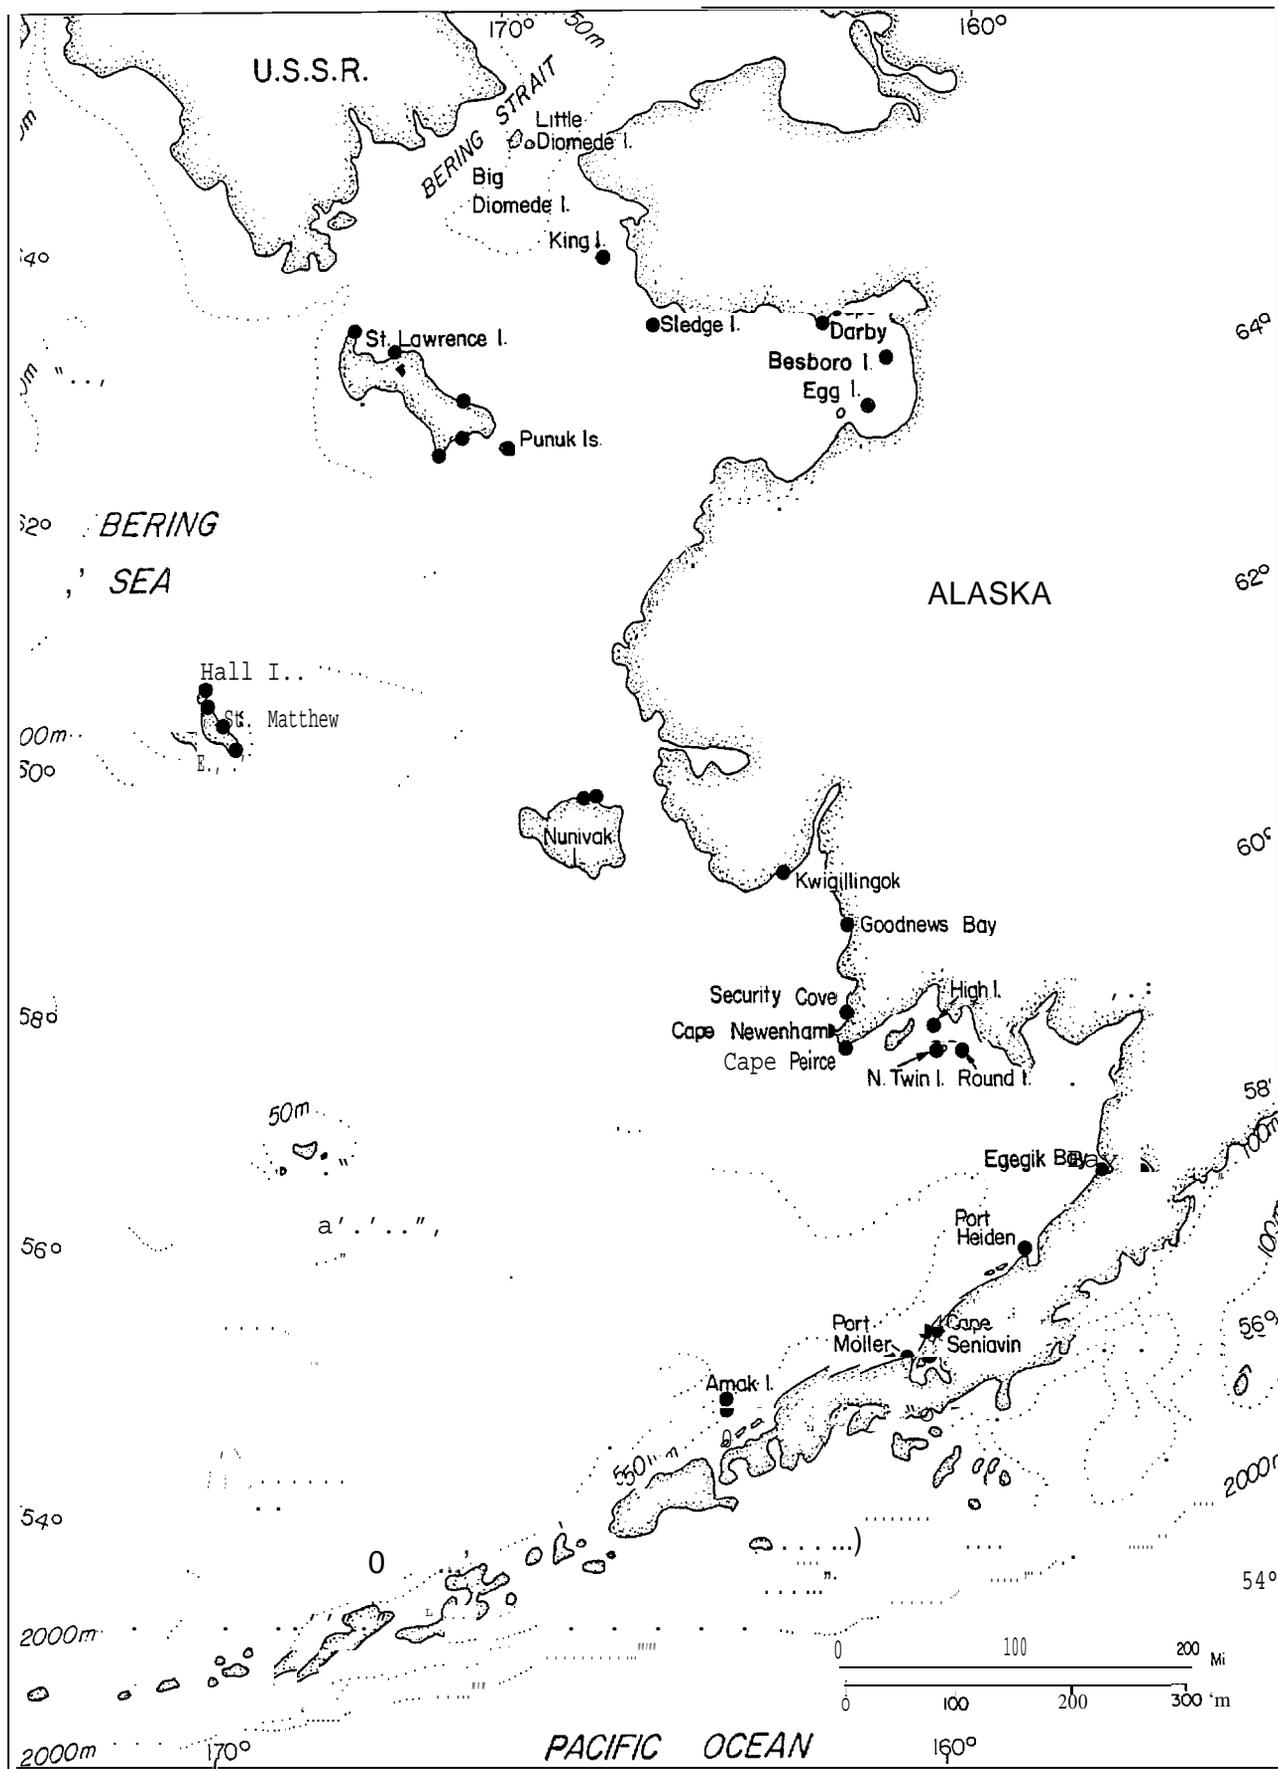

Figure 10. Locations of important haulout sites used by Pacific walrus in the Bering Sea, Alaska.

of day-to-day and week-to-week fluctuations in occupancy at **haulout** sites (Fig. 11).

Freedom from disturbance, particularly that associated with hunting and other types of harassment of hauled out walrus is required before reoccupancy of abandoned **haulout** sites is possible. Although walrus have been attempting to use former **haulout** sites and have been reported at many locations, relatively few places are protected from undue disturbance by man. An interesting comparison of successful vs. unsuccessful **reoccupancy** has occurred on the Diomed Islands. Big and Little Diomed islands are very similar to each other and are only 4 km apart. Walrus **haulout** sites were **re-established** on Big Diomed Island starting in about 1968. That island is now regularly used every year by several thousand walrus. In contrast, small numbers of animals have repeatedly attempted **to haul** out on **Little** Diomed Island, but are usually hunted and frightened away when discovered. As yet, **there** is no regularly used **haulout** site on that island.

Location and Status of Pacific Walrus **Haulout** Sites

Data from Frost et al. (1983) indicated that only 12 of 39 specific locations where walrus had been reported to haul out in the eastern Bering Sea were regularly used by substantial numbers of animals. Six of these major locations were in the North Aleutian Basin (**Amak** Island, Port **Moller**, Cape Seniavin, Big Twin Island, Round Island, Cape Newenham), one was in the St. Matthew Island-Hall **Island** area, and five were in Norton Basin (**Besboro** Island, St. Lawrence Island, Penuk Islands, King Island and Big Diomed Island (USSR)). Except for the addition of Cape **Peirce**, which is currently used by a large proportion of the walrus that historically have hauled out **in** the Walrus Islands area, we found the general trend given in Frost et al. (1983) to be generally consistent with our current review (Table 7; Fig. 10; Appendix 5); we evaluated about **30** different **haulout** sites for Pacific walrus.

It is noteworthy that the **reoccupancy** by significant numbers of walrus of **haulout** sites in the southern Bristol Bay area, and some sites in northern Bristol Bay (e.g., Cape **Peirce**), is a relatively recent event. It is thought that these sites were abandoned earlier in the century when walrus numbers

† Note: data in this table are from many different sources and have not been collected in a consistent or systematic manner. Peak counts were taken from the following sources: Kenyon (1960); Fay and Kelly (1980); Kelly (1980); Fay (1982); Frost et al. (1983); Mazzone (1986); O'Neil and Haggblom (1987); Sherburne and Lipchak (1987); S. Hills (USFWS, pers. comm. 1988); ADFG files; Izembek NWR files; NMFS files; USFWS files.

* An asterisk indicates that this haulout site is occupied mostly by adult males. All other haulout sites (those without asterisks) are occupied mostly by male and female adults, subadults and calves.

"-" signifies that no data are available.

were considerably reduced. Some of the **first** relatively recent **sightings** in the southern **Bristol Bay region** were on Amak Island **in spring** 1962 (J.J. Burns files), near Ugashik Bay in spring 1962 and 1963 (Fay and Lowry 1981), and on ice in **Herendeen Bay** (Port **Moller** area) in late winter-early spring 1968 (Frost et al. 1983). Cape Seniavin apparently was reoccupied in the late 1970's. The largest number of walrus recorded **along** the north coast of the Alaska Peninsula was 6,750 individuals on 26 April 1983. About 3,500 of these were hauled out at Cape Seniavin and 3,250 were in the Port **Moller** area, including **Herendeen Bay** (USFWS file data).

Reactions of Pinnipeds to Disturbance

The following section of the report describes documented reactions of northern fur seal, northern sea lion, harbor seal and Pacific walrus to various types of noises and disturbances **similar** to those that may result from OCS development **in** the eastern **Bering Sea**. As mentioned **in** the 'Methods' Section, we have used published information as much as possible, but also have relied on relevant personal communications from experienced and knowledgeable biologists. We have also used relevant published and unpublished information concerning species or subspecies closely related to the four pinnipeds considered **in** this study, e.g., Guadalupe and Cape fur seals (Arctocephalus townsendi and A. pusillus), respectively, California sea lion (Zalophus californianus), spotted seal (Phoca largha), ringed seal (P. hispida), bearded seal (Erignathus barbatus), harp seal (P. groenlandica), and Atlantic walrus (Odobenus rosmarus rosmarus).

Our discussion of the effects of noise and disturbance is organized by the four species, but is further broken down into three additional categories, namely: airborne noise and disturbance (mainly aircraft), underwater noise and disturbance (mainly ships and boats), and human presence and disturbance. Airborne and underwater noises and disturbances are further subdivided into stationary sources and moving sources. Several recent observations suggest that animals are more likely to accommodate to stationary noise sources than moving sources (see Richardson et al. 1983 for review).

Northern Fur SealAirborne Noise and Disturbance

Moving Sources. A **well** documented example of aircraft disturbance to northern fur seals occurred at the **Gorbatch** hauling grounds on St. Paul Island (**Pribilof** Islands) in September 1981 (S. **Swibold**, **pers. comm.** 1988). **Swibold** was photographing from a blind near thousands of resting bachelor bull fur seals. As a **large** twin-engine aircraft passed overhead (at 300-500 feet altitude), the seals panicked and stampeded toward the water. Her film apparently shows the seals looking up (toward the low-flying aircraft) as they stampeded. No mortality was recorded as a result of this disturbance.

In contrast to the above observation, was an observation during July of a group of sleeping **subadult** male northern fur seals at a hauling ground adjacent to East Rookery, on St. George Island in the **Pribilofs**. As a twin-engine cargo plane flew directly overhead at low altitude (S. Zimmerman, **NMFS, pers. comm.** 1988), the **seals** responded by awakening and lifting their heads, but there was no mass movement, no milling **behavior**, nor any other obvious overt reaction to the aircraft.

In the opinion of C. **Fowler** (**NMFS, pers. comm.** 1988), the Little **Polovina** rookery/hauling ground may be the next fur seal **haulout** site to be abandoned in the **Pribilof** Islands--possibly within the next several years. This **haulout** site is within 5 km of the airport runway on St. Paul Island, and one fur seal biologist (A. York, **NMFS, pers. comm.** 1988) speculated that the decline in numbers of fur seals at the **Polovina** Complex (**Polovina**, Little **Polovina** and **Polovina** Cliffs; see Fig. 15, Appendix 2) of rookeries may be related to their close proximity to the St. Paul airport.

York tried to document the number of commercial aircraft using the **St. Paul** airport each year since its construction during **WW II** (1941-1943) in relation to the steady decline in the number of fur seals using the **Polovina** Complex of rookeries. Although the airport records showed a general increase over the years in the number of commercial flights to and from St. Paul, there were many more unrecorded military and charter flights that she was unable to

document. Although her investigation was inconclusive, York felt there was no basis to completely discount the possible relationship between the level of aircraft overflights and the decline in use of the **Polovina** complex of rookeries/hauling grounds, especially at **Polovina** and **Little Polovina**.

York said that on several occasions during the past few years she has observed large helicopters flying over her study area at the Kitovi rookery on St. Paul Island. However, she has never noticed a stampede as a result of these overflights.

In the opinion of A. **Antonelis** (NMFS, pers. comm. 1988), fur seals respond differently to different types of aircraft. When he conducted photo-censuses using a single-engine, fixed-wing aircraft flying at 100-175 m over the fur seals, he saw no overt reaction by the seals to his aircraft. However, he was aware of severe disturbances caused by larger multi-engine aircraft flying low over rookeries/hauling grounds. **Antonelis** has seen the film by **Swibold** and noted that it is a clear example of severe aircraft disturbance to northern fur seals. He further pointed out that fur seals seem to be more easily disturbed (i.e., are more inclined to stampede) on hot rather than cool days. **Antonelis** reiterated that he was not aware of any instance where mortality has resulted from a low-level aircraft overflight.

Stationary Sources. A. **Antonelis** (NMFS, pers. comm. 1988) is currently conducting research and synthesizing information on the effects of sonic booms on fur seals at San Miguel Island, California. His research is primarily related to possible hearing impairment in the seals caused by sonic booms associated with activities at the nearby Pacific Missile Range (Vandenberg Air Force Base) in California. He has found no example in a fur seal of hearing impairment caused by a sonic boom. Based on his observations, fur seals usually respond to sonic booms by assuming an upright posture (**they appear startled**), and they sometimes stampede from the beach into the water. **Antonelis** has never seen a case where mortality has resulted from such disturbance.

Underwater Noise and Disturbance

Moving Sources. During his pelagic studies of northern fur seals, H. Kajimura (NMFS, pers. comm. 1988), has found them to be quite tame when first encountered at sea; they are curious and often approach the research vessel. However, after one or two days of collecting (hunting) northern fur seals in one area, it is often very difficult to maneuver the ship close to the seals. In some instances, sleeping fur seals were seen to respond to the approaching ship at distances up to about a mile; the seals apparently were awakened by the noise of the ship, and then rapidly swam away. Kajimura said that he thought the seals were responding to the sounds of the ships propellers and engine, He thought they could hear the prop and engine sounds, and that they associated those sounds with earlier collecting activities and fled away from the source of the ship sounds. However, such a response could also, in part, be an artifact of removing (hunting) the least wary seals from an area.

Stationary Sources. Shaughnessy et al. (1981) reported on attempts to scare cape fur seals away from fishing nets in waters off southern Africa. The seals disturb shoals of fish and pursue fish into nets, causing damage to the nets. Fur seals remained in an area where they were subjected to 'firecrackers' , killer whale playbacks, rifle shots and an arc-discharge transducer. The arc-discharge transducer produced pulses at 10-second intervals with a peak source level of 132 dB//1 μ Pa at 1 m. Fur seals did not appear to be deterred by any of the devices used in this study.

Human Presence and Disturbance

According to C. Fowler (NMFS, pers. comm. 1988), the abandonment of the 'Lagoon' rookery on St. Paul Island in the late 1940's may have been due to increased activities at the village of St. Paul, which is situated directly across the bay from the 'Lagoon' rookery. Fowler speculated that increased hunting, as well as increased general activity at the village of St. Paul, including the operation of the fur seal by-products processing plant, may have been responsible for the abandonment of this rookery.

A. York (NMFS,pers.comm. 1988) said that people (including biologists) walking near or through fur seal rookeries/hauling grounds also may cause major disturbances. In some cases, such disturbances may be as severe as aircraft overflights. According to York, one reason why there is so little documentation of mortal effects of aircraft overflights or other disturbances and consequent stampedes in breeding rookeries, is because observers are often too far away from the rookeries to be able to see dead or dying pups that may have been crushed during stampedes. Most of the observation blinds at the rookeries on the **Pribilof** Islands are far enough away to greatly reduce the possibility of human disturbance. Blinds near the hauling grounds may be closer to concentrations of seals, so there is a greater risk to the non-breeding animals concentrated at those locations.

Northern Sea Lion

Airborne Noise and Disturbance

Moving Sources. **Calkins** (1983) indicated that different types of aircraft appear to have substantially different effects on marine mammals. Reactions of northern sea lions to aircraft is varied and depends on several factors. At **haulout** sites where sea lions are not breeding and not pupping, approaching aircraft will usually cause some disturbance, frightening at least some animals into the water. On some occasions at **haulouts** (not rookeries), approaching aircraft can cause complete panic and stampede all sea **lions** to the water. The variability in reaction at **haulouts** (as opposed to rookeries) appears to depend on environmental conditions (weather, tide, etc.) as well as the type, speed and altitude of the approaching aircraft.

When sea lions are at rookeries during the breeding and pupping season, their reaction to aircraft is altered and appears to depend more upon the sex, age and reproductive status of the individual (R. Merrick, NMFS, pers. comm. 1988). **Immatures** and pregnant females may enter the water when aircraft approach, but territorial males and females with small pups generally remain hauled out, but may vocalize during the disturbance. In general, aircraft disturbance to sea lions appears to cause at least some panic stampedes into

the water on most occasions. **Merrick** knew of very few examples of serious disturbance to northern sea lions in the Bering Sea by aircraft flying within several hundred meters.

Stationary sources. Stewart (1981) reported that breeding California sea lions and elephant seals exposed to intense impulsive airborne noise from a carbide pest control cannon apparently were not greatly affected, although the details of this study are not available. Apparently 'Habitat use, population growth, and pup survival of both species were unaffected by periodic exposure to carbide cannon impulse noise' (Stewart 1981).

Underwater Noise and Disturbance

Moving Sources. Northern and California sea lions have been hauling out since 1978 on the **Steveston** jetty, adjacent to the middle arm of the Fraser River where it flows into Georgia Strait, in southwestern British Columbia (**M. Bigg, DFO, pers. comm. 1987**). They aggregate in this area in **April** and May to feed on **smelt** which move into the Fraser **River**. The haulout site is immediately adjacent (<500 m) to **the** main shipping channel leading from Georgia Strait to New Westminster, British Columbia. Bigg said there is no evidence that these sea lions have been affected by nearby heavy ship traffic or by tour boats that approach close to the hauled out sea **lions**.

Similarly, at Race Rocks, in Jaun de Fuca Strait, British Columbia, up to 800 California and northern sea lions haul out near a busy shipping lane leading to ports in **Puget Sound**, Washington, and Georgia Strait, British Columbia (**M. Bigg, DFO, pers. comm 1987**). This haulout site has been heavily used by sea lions in spite of increasingly heavy ship traffic over the past two decades. Bigg knows of no major disturbance to sea lions at the Race Rocks haulout site.

Bigg mentioned that northern and California sea lions aggregate (major "rafting area") in Active Pass, British Columbia, a narrow and heavily used shipping lane through the southern Gulf Islands of British Columbia. He is not aware of any disturbance to sea lions in this area, even though such shipping has been going on near "rafting" sea lions for many decades. **J.J. Burns** has

observed northern sea lions actively congregating around and following vessels engaged in fishing and processing of fish in the Gulf of Alaska and the Bering Sea.

Human Presence and Disturbance

Lewis (1987) studied the effects of human disturbance on sea lions at rookeries in the northeast Gulf of Alaska. Here census procedures (by biologists) involved purposely flushing all animals except pups from the rookeries. Results indicated that there was little pup mortality as a result of this procedure, but that aggressive behavior and territorial behavior by breeding females increased significantly, and the rookery was much more easily disturbed (more stampedes) by natural events after such a disturbance. There was some abandonment of the rookery by non-pup sea lions immediately after the disturbance. The significant finding, however, was that there was markedly lower maintenance of female-pup contact (49% vs. 71%) in the year of disturbance compared to a year of no such disturbance. The female-pup bond during the early stages of pup development is critical to the survival of the pup; if this bond is broken, the pup is likely to die. It should be noted that natural mortality of pups during the first year of life may reach 50% (ADF&G 1973). The variety of natural mortality factors is not clearly understood, but young pups washed to sea during storms are presumed to drown.

Northern sea lions are generally less easily disturbed at rookeries early in the breeding season (June) during mating and pupping, and generally more sensitive later, after the breeding season (August), when most of the adult males and non-breeding females are hauled out at locations away from rookeries (R. Merrick, NMFS, pers. comm. 1988). During August, only the pups and productive females would still be present near rookeries; Merrick said that this is the period when sea lions are most reactive to disturbance.

According to Merrick (NMFS, pers. comm. 1988), the shooting of northern sea lions has caused severe disturbance in the Unimak Pass area of the Bering Sea. In the past, sea lion meat apparently was used as bait in certain commercial fishing operations (e.g., crab fishery, long-line halibut fishery); sea lion rookeries near fishing grounds traditionally were hardest hit by such

activities. Although this practice is no longer **common**, the large rookery on **Ugamak** Island recently was affected by such a shooting. Similarly, **Kenyon** (1962) suggested that the large northern sea lion rookery near Northeast Point on St. Paul **Island** was abandoned because of excessive harvesting. Formerly, this was the largest sea **lion** rookery in the **Pribilof** Islands; **no** pups have been recorded there since **1957**.

Harbor Seal

Airborne Noise and Disturbance

Moving Sources. Pinnipeds that haul out for molting or **pupping** probably are the most susceptible to adverse effects resulting from disturbance by aircraft. Johnson (1977) gave evidence that harbor **seals** may temporarily leave pupping beaches when aircraft fly over. Since harbor seals may not always haul out at the same site when returning to the **beach**, pups **left** behind at one site may be permanently **separated** from their mothers and may die. Low-flying aircraft may have been responsible for the deaths of more than **10%** of the approximately **2000** pups born on Tugidak **Island**, Alaska, in 1976 (Johnson 1977). **All** types of aircraft flying **below** 400 ft (122 m) **nearly** always caused seals to vacate the beaches, sometimes for 2 h or **more**, with helicopters **being** particularly disturbing. Responses of harbor **seals** to overflights at altitudes between **400** and **1000 ft** varied with weather, frequency of disturbance, altitude and aircraft type. Aircraft were more disturbing on **calm** days, after recent disturbance, and at lower altitudes. According to Johnson (1977), helicopters and **large** planes were more disturbing to harbor **seals** than small airplanes.

Pitcher and **Calkins** (1979) reported that harbor seals are susceptible to disturbance from low-flying aircraft and are noted for their mass exodus (stampedes) from hauling areas in the event of such disturbance. As mentioned earlier, Johnson (1977) has warned that one of the major negative consequences of such stampedes is the separation of mother-pup pairs, and the **consequent** reduction in pup survival.

Several thousand harbor seals haul out during May through October on the sand and mud bars at the entrance to Nanvak Bay, near Cape Peirce, Alaska (Johnson 1975; USFWS file data; LGL file data). Single-engine float planes and less frequently small amphibious aircraft land and take off near the beach about 2-3 times each month during this same period. During these aircraft activities, the seals appear to leave the beach as soon as the aircraft either land or take off.

M. Bigg (DFO, pers. comm. 1988) said that there are two major haulout sites for harbor seals on the sand bars and shoals near the entrance to the Sea Island Arm of the Fraser River, in British Columbia. One of these haulout sites (the northernmost) is fairly close to the main E-W runway at Vancouver International Airport. Aircraft frequently fly low over this haulout site with little or no reaction by the harbor seals, which Bigg thinks have habituated to the noise/disturbance. Hovercraft, on the other hand, do frighten these seals into the water. Bigg speculated that the noise from a hovercraft was "probably 10 times greater than the aircraft flying overhead". Since the hovercraft operates on the water, it is possible that the seals perceive it as more of a 'threat' than the more numerous aircraft overhead.

Spotted seals are closely related to harbor seals, and also haul out on beaches along the Bering Sea coast (Burns 1970). Burns and Harbo (1977, in Cowles et al. 1981) reported that spotted seals react to aircraft at rather great distances by 'erratically racing across [ice] floes and eventually diving off'. This type of 'panic' reaction also may be common during summer when spotted seals are hauled out on beaches. However, disturbance by aircraft at terrestrial haulout sites is unlikely to cause pup mortality because spotted seal pups are usually independent by summer when they might be hauled out at terrestrial sites. Nevertheless, Eley and Lowry (1978) speculated that spotted seals may abandon summer haulout sites if disturbed frequently.

Burns and Harbo (1977) found that reactions by ringed seals on fast ice to an aerial survey aircraft were variable depending on proximity to high headlands, position of the aircraft in relation to seals, and weather conditions. When transects were within 2 miles of a rock cliff, most seals hauled out adjacent to the cliffs dived through nearby holes and ice cracks as

the aircraft came abreast or over them. Seals under the aircraft dived even when those to the side did not. Reactions on nice days *were* less severe than on marginal days for surveying, and seals overflown during optimal haulout conditions often shifted positions and looked upward at the aircraft but did not **dive**.

Burns and Frost (1983) reported that "Bearded seals usually react mildly to **an** airplane even at close **range**. They almost always raise their heads, frequently look Up at the plane and **usually** remain on the ice unless **the** plane passes directly over them." "On a warm calm spring day when they are basking, they often show little concern for a low-flying aircraft." "Low-flying **aircraft**, especially helicopters frighten seals resting on the ice. This kind of disturbance can be minimized by requiring normal flight altitudes higher than 2,000 feet, by short climbs and descents from installations in bearded seal habitat and by use of the shortest, most direct flight **routes**." In general, bearded seals appear to be only **mildly** affected by aircraft overflights, usually showing some reaction only at very low altitudes,

Stationary Sources. A **small** population of harbor **seals** resides in upper Kachemak Bay, Alaska, near where the Bradley Lake Hydroelectric Project is under construction. During 22 May to 17 June **1987**, before construction activity had begun at the site, *as many as 150-200* seals have been *seen hauled* out in groups of 50-75 on bars in the upper bay near the construction site (Roseneau 1988). The **seals** typically haul out at a location about **1.6** km from the project powerhouse site and permanent construction facilities. During construction activities in the area (late June through October) the **seals** appeared to ignore most project activities, and no marked changes in overall numbers or patterns of use were noted during construction activities or after project activities ceased during 1987 (D. Trugden, pers. **comm.**, in Roseneau 1988).

Underwater Noise and Disturbance

Moving Sources. **Ugashik** Bay in upper Bristol Bay, Alaska, supports a relatively large population of harbor seals (about 400-500). The seals occupy the bay along with many diesel-powered commercial fishing boats and

noises emanate from the processor, including noises from large compressors. Small outboard-powered skiffs from Pilot Point, Alaska, also operate throughout the bay. Harbor seals remain in Ugashik Bay despite these activities (R. Gill, USFWS, pers. comm. 1987).

J.J. Burns (pers. obs. 1988) observed two groups of harbor seals (200 to 400 seals in each group), many of which were pups hauled out during daytime low tides on 9, 11, 13 and 14 July 1988 in Ugashik Bay. This was during the peak of fishing operations in the area and numerous fishing boats continuously passed relatively close to the animals. Fishing activity had been going on since about mid-June. It was noted that the seals paid little attention to moving boats that were at least 200 m away. The seals became alert and agitated when boats stopped at that same distance and some animals slowly (not in a stampede) entered the water when boats approached closer than 150 to 200 m. All seals vacated the **haulout** site when boats approached closer than about 60 m. The **haulouts** were submerged at high tide and the seals became broadly scattered through the fishing fleet, occasionally feeding on salmon hanging in gill nets.

Thousands of harbor seals haul out near Port **Moller** (Pitcher 1986), on the north side of the Alaska Peninsula. In this area, a large fish-processing vessel is stationed for most of the summer fishing season; many fishing boats deliver catches to the processor vessel each day (R. Gill, USFWS, pers. comm. 1987). During these deliveries, the fishing boats, including outboard-powered skiffs and tenders, motor through a channel close to the hauled out seals, apparently causing little if any disturbance to the resting animals.

M. Bigg (DFO, pers. comm. 1988) said that there are two major **haulout** sites for harbor seals on the sand bars and shoals near the entrance to the Steveston Arm of the Fraser River, in British Columbia. According to Bigg, harbor seals at these sites have become habituated (do not respond) to nearby fishing boats that pass quite close to the haulout sites.

Few authors have described responses of seals to ships or boats. **Kapel** (1975) noted that hunters in one part of Greenland are opposed to the use of outboard motors because they think that they frighten seals away. In fact,

pinnipeds may associate the boat noise with being hunted (H. Kajimura, NMFS, pers. comm. 1988), and thus they may be reacting to the threat of being hunted rather than the noise of the ship or boat.

Murphy and Hoover (1981) noted that "**Disturbance** may have considerable impact where **haulout** space is limited, since seals frightened from **haulouts** tend to search for new sites rather than use those they **abandoned...**".

In **Bonner's** (1982) review of human-related impacts on **seals**, he states that "**Drescher** (1978) has drawn attention to the need of harbor **seals** for an undisturbed nursing period. Disturbance by passing sailboats or power craft can seriously reduce the survival of **pups**".

Terhune **et al.** (1979) obtained qualitative information about the amount of harp seal vocalization before and after a 36.5 m stern trawler approached within 2 km of a pupping area in the offshore pack ice. There was little evidence of a decrease in vocalizations the first night after **the ship arrived, but** many fewer vocalizations were recorded after that. **It** was not **known** whether some seals moved away from the **pupping** area, or whether **all** remained but vocalized less often. The results were ambiguous because of temporal variation in vocalizations and varying levels of other disturbance, such as seal hunting. Ship sounds often were so intense that harp seal vocalizations (if any) were totally masked.

Brodie (1981a, 1981b) has pointed out that harp and hooded seals continue to return to traditional breeding and molting areas in the moving pack ice off Newfoundland each year despite centuries of disturbance by vessels and seal hunting. **It should** be pointed out that the **seals** have few options short of changing their habitat. Also, there are never any hunters present when the **seals** coalesce into the breeding herds on the ice in early March. The hunters wait until the herds have formed and pupping has begun before traveling to the floes for the hunt.

Stationary Sources. Anderson and Hawkins (1978) conducted a series of trials to study the effects of sound as a deterrent to predatory seals at an Atlantic salmon netting station. **A** feasibility trial and follow-up experiment

were conducted on a captive harbor seal. A variety of sounds were used in the trials; pure tones, killer whale calls, and loud noises were transmitted and responses were recorded on videotape. Although one sound appeared to cause an alarm reaction, the seal appeared to accommodate rapidly. Further field trials were conducted where grey seals were eating salmon at a river netting station. Although a broad range of sounds were played, none was consistently effective in scaring seals from the nets. The results of this study led to the conclusion that an acoustic deterrent for feeding seals is not effective. Thus, it is probable that harbor seals and some other **phocids** are quite tolerant to underwater sounds, especially when they are feeding in areas where prey are abundant. This conclusion is supported by a variety of recent studies that are summarized in the proceedings of a symposium on acoustical deterrents in marine mammal (almost solely pinniped) conflicts with fisheries (Mate and Harvey 1987).

Cummings et al. (1986) broadcast man-made noises associated with on-ice seismic (**Vibroseis**) activity to ringed seals on two occasions during **haulout** periods in March and April. On two occasions early in the season, sound production by seals before and after the broadcasts were not significantly different. During two broadcasts later in the season, sound production by seals was higher than recorded earlier. However, this increase was thought to be related to the timing of the breeding cycle in ringed seals rather than the sound broadcasts. In general, sound production by ringed seals was probably not affected by seismic activity noise.

Human Presence and Disturbance

Allen et al. (1984) studied the effects of various types of disturbance on harbor seal **haulout** behavior in **Bolinas** Lagoon, California. Their results indicated that harbor seals were disturbed on 71% of days monitored; people in canoes were the principle source of disturbance. Human activities closer than 100 m caused seals to leave **haulout** sites more than activities at greater distances. On average, it took harbor seals 28 ± 21 minutes to **haulout** again after they were disturbed. After disturbances, the number of seals that hauled out again was lower than the original number. Based on results of other studies on the effects of human disturbance on harbor and monk seals, the

authors speculated that disturbances near Marin County **haulout** sites could cause harbor **seals** to switch to nocturnal **haulout** behavior, increase pup mortality, and/or cause **the haulout** site *to be* abandoned.

Osborne (1985) studied the effects of disturbance on a local population of harbor **seals** that **haul out in Elkhorn** Slough, California. She found that recreational boating, primarily canoes and power boats, were the **single** largest source of disturbance to hauled-out seals. **Boating** caused two-thirds of the seal flight reactions; most of the disturbance was in summer when recreational activity was greatest. All flight reactions occurred when the boats were within 100 m of the **haulout** site; 74% were when the boats were **less** than 30 m.

Laursen (1982) reported that coastal areas of the Dutch Wadden Sea where harbor **seals** haul out were receiving increasing recreational pressures. As numbers of people using beach and water areas **increased**, more harbor **seals** were being displaced from loafing areas. Analysis of data on the distribution of humans and **seals** showed that the first disturbing event of the day determined where **seals** were or were not found. Loafing harbor seals were present only in areas where **they** had not been disturbed earlier in the day, indicating it may take only one such disturbance to keep seals away from otherwise adequate loafing habitat for that day. This indicates that the timing and frequency of disturbance may be **an** important aspect of short-term displacement.

Reijnders (1984) reported that "Direct effects of disturbance on reproductive success of pinnipeds are unlikely to **occur**, as only very dramatic events--such as collisions or injuries--will cause intrauterine mortality or abortion. This is concluded from reports on heavily-hunted seal populations in which any differences between the rate of ovulating and pregnant females, **and** the differences between numbers of half-term-pregnant and parturient animals, were **neglectable** [sic] (Bigg, 1969; Smith, 1973; Boulva, 1974). " **Reijnders** (1984) *goes on to* state that "This is not unexpected, because hunting of seals **mainly** takes place between birth and weaning, and stress involved with those activities is of short duration. **It** is assumed, however, that more frequent

disturbance throughout the whole year might act indirectly to depress reproductive success through impairing reproductive performance."

During the daylight hours from 14-27 June 1980, **Renouf et al. (1981)** watched movements of harbor seals (and grey seals) through a narrow channel connecting their **haulout** sites with the sea. Seals used this channel to come and go from the sea after being forced from their **haulout** sites on nearby sand **flats** exposed at low tide. Before the study it was presumed that the seals returned to the sea to feed and/or to avoid disturbance. There was only a **slight** increase in seaward travel by seals after they were disturbed by humans at their **haulout** sites (automobile and boat traffic; tourists walking nearby and touching pups), and the seals did not always go to sea when the sand flats where they hauled out were flooded by the high tide.

It has been reported that hunting in the Shetland Islands (Scotland) has, in at least one place retarded the onset of the pupping season (**Tickeil 1970**). *However*, even those stocks which were heavily hunted continued to pup on their traditional hauling grounds rather than move to a new area (**Bonner et al. 1973**).

Terhune (1985) noted that "The seals readily enter the water in response to a wide variety of disturbances. They react in essentially the same manner when shot at, approached by humans *or* dogs walking along a beach, or approached by boats or light aircraft."

Walrus

Airborne Noise and Disturbance

Moving Sources. Walruses at terrestrial **haulout** sites may show responses to aircraft disturbance that vary with distance, aircraft type, flight pattern and age-sex class of the animals. Brooks (1954) noted that walruses onshore were disturbed by an aircraft passing overhead at 300 m. In a more extensive study, Salter (1979) found that, at horizontal distances beyond 2.5 km, the only response elicited by aircraft was raising of the head by some of the hauled out animals. A Bell 206 helicopter 1.3 km from a **haulout** site and

flying at an altitude of less than 150 m prompted orientation toward the **water** by 31 of 47 animals. When the helicopter veered suddenly causing **an abrupt** change in the pitch of the **noise**, 26 of 47 walruses rushed into the water (Salter 1979). Another **flight** by a Bell 206 helicopter at the same altitude **but** at a range less than 1 km elicited head raising and orientation toward the water **by** some animals but no escape reactions--presumably because there were no sudden changes in the flight pattern or noise. **DeHavilland Otter aircraft**, which have a piston-driven single engine, caused escape *reactions by walruses* at horizontal distances less than 1 km during overflights at altitudes of 1000 and 1500 m (Salter 1979). Disturbance observed by Salter never caused escape reactions in all the walruses at the haulout site. **Adult** females, **calves** and immatures were more likely than **adult** males to enter **the** water during disturbance. However, severe disturbance may cause stampedes into the water by **all** the walruses at a **haulout** site.

Loughrey (1959) reported that walruses started to scramble towards the water when **an aircraft** was **still** more than 400 m **away**, and had all reached the water by the time the aircraft passed overhead. The walruses were most disturbed by the noise of the aircraft when it **flew** overhead at **low** rather than high altitudes; he noted that some **calves** were crushed to death by walruses stampeding from low-flying aircraft. Tomilin and Kibal'chich (1975 in Fay 1981) reported that an overflight at 150 m by an **IL-14** twin piston engine aircraft caused a stampede by walruses that resulted in **21 calves** being crushed to death and two aborted fetuses.

Burns and Harbo (1977) found that walruses **hailed out** on ice floes at the Bering Sea ice front responded **in** a variable manner to aircraft overflights, depending on weather. Apparently the walrus were most sensitive to aircraft disturbance on cold, overcast days. They speculated that in general, aircraft disturbance was not anticipated to affect pup survival in the eastern Bering Sea, except under specific conditions at terrestrial sites on the **Punuk** Islands (**J.J.** Burns).

Salter (1979) observed no detectable response to six approaches by outboard-powered inflatable boats at distances of 1.8-7.7 km from walruses hauled out at a terrestrial site. Similarly, Brooks (cited in Fay 1981) said

that walrus hauled out on ice floes appeared not to be disturbed by the sound of outboard engines on small boats at distances of 400 m.

Frost et al. (1986) reported that "Fay observed instances when walrus at Cape Seniavin were stampeded into the water by low-flying aircraft. When animals flee from the hauling areas some mortality of animals. . . will occur through injury or abandonment and subsequent starvation. . . . Regular human disturbance has prevented the long-term use of haulouts at Cape Newenham, Sledge Island, and to some extent King Island (ADF&G, unpub. data)". The 'regular human disturbance' at Cape Newenham was not specified in Frost et al (1986), nor were any data presented. However, we presume they were referring to disturbance associated with regular activities at the U.S. Air Force Radar Station at Cape Newenham. Disturbances at King and Sledge islands were probably associated with boat and aircraft traffic from nearby Nome, Alaska.

Fay et al. (1986) reported on a series of disturbances to a herd of about 1,000 male walrus that had been under observation at a terrestrial haulout site at Cape Seniavin, in southern Bristol Bay. In one day (8 April 1981), over the course of 8 hours, three fixed-wing aircraft and one helicopter passed the haulout site at altitudes of 60-80 m and flushed all of the animals into the water. The number of animals remaining at the site after each of these overflights was not mentioned. However, by early morning of the following day (9 April) about 100 animals had returned to the haulout site, but about half of them left when another fixed-wing aircraft passed them at less than 100 m. About 100 walrus were present when observations started on the following day (10 April), but those were stampeded into the water about an hour later by another passing aircraft.

Fay et al. (1986) reported on another aircraft disturbance to walrus hauled out on a beach on the Penuk Islands (near St. Lawrence Island) on 8 November 1981. During that episode a twin-engine aircraft (type unspecified) made three passes at an altitude of about 60 m over about 4,500 walrus. About 1,000 of the animals raised their heads when the aircraft passed, but fewer than 100 of them went into the water. Two other aircraft passed within hearing range of the Penuk Islands that same day, but caused no apparent response among the walrus.

Similarly, **Roseneau** (1988) reported that walrus haulouts along rocky beaches near the Air Force Station at Cape Lisburne often ignored low-flying aircraft. In one case, a group of about 50 sleeping walrus were not disturbed (did not respond) when a 4-engine Hercules C-130 cargo aircraft took off from the Air Force station and flew within 0.8 km of the resting animals. According to **Roseneau** (1988), "Noise from the climbing, departing aircraft flushed many seabirds, but the walrus did not respond to the **disturbance.**" **Roseneau** also notes that "Some aircraft-related disturbances of walrus have **almost** certainly occurred at Cape Lisburne over the years, Site personnel have related several **incidents...**of groups flushing from landing aircraft when animals have been **hauled** out near the western end of the runway. . . . However, the arrival of varying numbers of summering and migrating walrus remains an annual event."

The consequences of aircraft disturbances to walrus is discussed by Fay et al. (1986), but most of their discussion relates to disturbances of females and calves haulouts on **ice**, or of disturbances to wintering or breeding animals. They do not discuss the consequences of disturbance to walrus haulouts at terrestrial sites. However, Fay and **Kelly** (1980) recorded a case of mass natural mortality apparently caused through injury during a stampede of several thousand walrus during late autumn 1978 at terrestrial haulout sites on eastern St. Lawrence Island and on the **Punuk** Islands (located southeast of **St.** Lawrence Island). Fay and Kelly (1980) estimated that about 148,000 walrus had **hauled** out at six major sites on St. Lawrence Island and the **Punuk Islands** during autumn 1978. They estimated the following spring (June 1979) that about 411-1134 **walrus** carcasses (range; based on aerial survey results) were present on the coast of **St.** Lawrence Island; most of the carcasses had apparently drifted away from the haulout sites and had washed up at 'non haulouts'.

The details of the above incident are best quoted from Fay and Kelly (1980:227-228). ". . .At the time when these **events** occurred, the weather was very **stormy**, with high winds and heavy seas from the south. The walrus, mainly adult females and young, were arriving from the northwest, presumably having swum from the edge of the pack ice which was then just north of Bering Strait, some 300 km away. The Eskimos remarked that the animals coming ashore appeared weak and physically exhausted, sleeping so soundly that it was

possible to walk up and touch them without waking them. Observers on the **Punuk** Islands in early November estimated that there were at least 6000 walruses on the beach at one time. Hunters camped at **Kialegak** Point [about 40 km W of the Punuk Islands; on St. Lawrence Island] stated that the animals covered about 2.5 km of beach and, **in** some places, extended inland onto the tundra.

According to the reports from Eskimos camped on **Punuk**, a few adult bulls were present among the females. These bulls were extremely belligerent, rushing through the resting herd to engage other bulls in battle. On one occasion, two bulls fought with such **vigour** that one appeared to have mortally wounded the other. In their rushes through the herd, the bulls trampled and struck at other animals with their tusks, and some calves (about 6 months old) were believed to have been killed by them. One night, an entire herd stampeded off the beach into the sea, leaving behind about 25 dead and disabled animals at the water's edge, below a wave-cut terrace. . . ."

According to biologists working at the Cape Peirce **haulout** sites since 1983 (D. Fisher, USFWS, pers. **comm.** 1988) low-flying (<500 ft ASL) single engined aircraft have disturbed walrus hauled out on the beach near the entrance to Nanvak Bay on several occasions. During one incident in summer 1986, an aircraft flew low (<500 ft ASL) over 4000-5000 hauled out animals several times and caused a stampede into the water that resulted in 2-3 animals being trampled and killed.

Human Presence and Disturbance

Frost et al. (1983) mentioned that "We have noted that . . . walruses almost invariably flee into the water when approached by humans. . . ." Similarly, Kelly (1980) reported that walruses will leave **haulout** areas in response to the presence of man, and speculated that continued harassment may prevent recolonization.

Shooting of walrus at Cape Peirce by passing boaters and aircraft has been a chronic problem at this site (D. Fisher, USFWS, pers. **comm.** 1988). During summer 1983 at least 20-23 walruses were shot and killed on the beach near the entrance to Nanvak Bay by a passing boater or a low-flying aircraft (D. Fisher, USFWS, pers. **comm.** 1988).

DISCUSSION

We have evaluated **haulout** sites used by fur **seals**, sea lions, harbor **seals** and walruses in the eastern Bering Sea in an objective and quantitative manner in an attempt to determine which sites appear to **be** most sensitive to disturbance. Our IPSI evaluations were based on eight different (but sometimes related) criteria (see 'Methods') for each **haulout site**, and are presented and discussed here **on a** species-by-species basis.

Northern Fur Seal

This species differs from the other three pinnipeds considered because virtually **all** animals **haulout** in the study area at sites on the **Pribilof** Islands, although there is a relatively new and **small haulout** site **on Bogoslof** Island, in the eastern Aleutians. Lloyd et al. (1981) speculated that the feeding habitat of fur seals consists of outer continental **shelf** and oceanic domains, and that **"only** islands in or immediately adjacent to the [very productive] outer shelf domains are suitable for fur **seal** rookeries."

In addition, virtually all **haulout** sites are used by **all** age and sex classes of northern fur **seals** that haul out on an annual **basis**, even though these classes may be segregated in different sections of the site (see Appendix 2 for maps of **haulout** sites **on the Pribilof** Islands). The northern fur **seal** is also unique because it does not haul "out except during the breeding and post breeding season; it is pelagic throughout most of the year.

There is considerable evidence that northern fur seals respond to various forms of disturbance in different ways (see 'RESULTS'). However, there is no direct evidence that significant mortality has resulted from any of the recent disturbances that have occurred at **haulout** sites. Most of the recent disturbances are similar to those that may accompany OCS development (e.g., aircraft overflights at altitudes <500 m, nearby ship traffic, human presence). It **should** be noted, however, that this subject has not been thoroughly investigated through field experiments (R. Gentry, NMFS, pers. comm. 1987).

There is circumstantial evidence that some formerly used historic sites were abandoned because of proximity to man. Overharvesting-overshooting and other chronic disturbances may have been significant factors in the abandonment of the Lagoon rookery on St. Paul Island and the Little Eastern rookery on St. George Island. Both of these **haulouts** were close to village sites (Jordan and Clark 1898). Also, some workers are concerned that there may be a relationship between low-level (<500 m) aircraft flights on St. Paul Island and the declining numbers of northern fur seals at the **Polovina** complex of rookeries which are located near the airport (A. Yorke, NMFS, pers. comm. 1988).

Based on all criteria considered in this study, including the general sensitivity of this species, and the susceptibility of the 22 **haulout** sites to disturbance, North Rookery on St. George Island, **Vostochni**, **Zapadni**, **Tolstoi**, Reef, **Polovina** Cliffs and **Gorbatch** rookeries on St. Paul Island, and Sivutch Rookery south of St. Paul Island rated highest in our IPSI evaluation scheme (Table 8). In particular, the **Polovina** Cliffs rookery is thought by some workers (C. **Fowler**, NMFS, pers. comm. 1988) to be a likely candidate for abandonment in the near future.

As mentioned earlier, there is some evidence that mortality of younger age classes at sea, through entanglement in abandoned fishing nets and other debris, is an important cause of the recent severe declines in numbers of northern fur seals (**Fowler** In press; 1985). Because of this decline, the National Marine Fisheries Service recently (May 1988) listed the **Pribilof** Islands population of northern fur seal as 'depleted' under terms of the Marine Mammal Protection Act of 1972.

Northern Sea Lion

Unlike northern fur seals, northern sea lions may haul out at terrestrial sites throughout the year. Nevertheless, there are definite seasonal peaks in **haulout** activity in the Bering Sea, especially at the breeding sites, or rookeries. Virtually all of the important rookeries in the study area, with the exception of Walrus Island in the **Pribilofs**, are in the eastern Aleutian Islands or southeastern Bristol Bay. Similar to northern fur seals (Lloyd et

Table 8. Inter-site Population Sensitivity Index (IPSI) for northern fur seal haulout sites in the Bering Sea, Alaska.

Max. Counts are Breed. Bulls only from either "1980's" or "Curr. Est." columns in Table 3.

Mean Max. Counts are Breed. Bulls only from "1960's" "1970's", "1980's" and "Curr. Est." columns in Table 3.

Proportion of Population is calculated from "Curr. Est." column in Table 3.

Age/Sex Composition x Activity values are based on whether all age/sex classes are present and whether breeding occurs regularly at the site (all=1, ad=2, subad=3), and the number of different locations at the site where fur seals haul out (1=many, 2=several, 3=few).

Duration of Use of site is the approximate proportion of the year that the site is occupied.

Consistency of Use categories areas follows: 1 = annual and consistent, and 2 = inconsistent.

Site Characteristic values were based on topography and proximity to noise/disturb. near the haulout site

(1=any site near noise/disturbance, 2=cliffs, 3=bluffs/slopes, 4=low or no relief).

Species Characteristics values were assigned based on the degree of sensitivity of the species

and potential for mortality as a result of noise/disturbance (1=high, 2= medium, 3=low).

al. 1981), **it** may be possible that the locations of northern sea lion rookeries in part are determined by the distribution and abundance of their principal prey, walleye **pollock** (Frost and Lowry 1986; Loughlin 1987; Bakkala et al. 1987), which in turn may be affected by overfishing and/or oceanographic characteristics.

Consistently used **haulout** sites are generally located in the southern half of the Bering Sea, south of Cape Newenham and the **Pribilof** Islands. **Haulout** sites farther north are generally used for shorter durations and less consistently from one year to the next (J.J. Burns, pers. obs. 1988).

Northern sea lions respond to noise and human disturbance in a variety of ways. There have been instances where human disturbance at northern sea lion rookeries has caused mortality (Lewis 1987; R. Merrick, NMFS, pers. comm. 1988). Thus, human disturbance has the potential to significantly affect the health of the Bering Sea population. Our evaluation of the sensitivity of northern sea lion: at their 26 terrestrial **haulout** sites in the study area has been influenced by the fact that mortality associated with disturbance is known to occur. Based on all criteria considered in this study (IPSI evaluation), including the general susceptibility of this species, and the susceptibility of the 26 **haulout** sites to disturbance, we determined that the rookeries and associated hauling grounds on **Ugamak** Island and nearby rocks and islets (**incl.** Round I.), at Cape Morgan on **Akutan** Island, on Sea Lion Rock near Amak Island, on Walrus **Island** in the **Pribilofs**, on **Bogoslof** Island, and at Billings Head on Akun Island rated the highest in our IPSI evaluation scheme (Table 9). Recent severe disturbances at the **Ugamak** Island rookery, and increased chronic disturbances from aircraft and ship traffic near Sea Lion Rock (close to the airport at Cold Bay, AK) and **Bogoslof** Island (increased fishing activity nearby) are of particular concern.

The history of use and disuse of **haulout** sites in the **Pribilof** Islands is of particular interest, considering that these islands are likely to be the focus of activity during possible OCS development in the St. George Basin. Of the eight historically used sea lion **haulout** sites in the **Pribilofs** (4 on St. George, 1 on St. Paul, and 3 on smaller surrounding islets), there is current information (1980's) for only 3 sites (Walrus I., Otter I. and **Dalnoi** Pt.

Table 9. Inter-site Population Sensitivity Index (IPSI) for northern sea lion haulout sites in the Bering Sea, Alaska.

Max. Counts are Ads./Subads. only from either "1980's" or "Curr. Est." (whichever is larger) in Table 5.

Mean Max. Counts are Ads./Subads. only from "1960's", "1970's", "1980's" and "Curr. Est." columns in Table 5.

Proportion of Population is calculated from "Curr. Est." column in Table 5.

Age/Sex Composition x Activity values are based on whether all age/sex classes are present and whether breeding took place at the site (all=1, adults and subad.=2), and the number of different locations at the site where sea lions haul out (1=many, 2=several, 3=1 or 2).

Duration of Use is the approximate proportion of the year the site is occupied.

Consistency of Use categories areas follows 1=annual and continuous, 2=annual but discontinuous, and 3=inconsistent.

Site characteristic values were based on topography and proximity to noise/disturb. near the haulout site (1=any site near noise/disturbance, 2=cliffs, 3=bluffs/slopes, 4=low or no relief).

Species characteristics values were assigned based on the degree of sensitivity of the species and potential for mortality as a result of noise/disturbance (high=1, medium=2, low=3).

* Asterisks indicate that the haulout site is a rookery.

area). Formerly there were four rookeries on the **Pribilofs**: Walrus Island; near Northeast Point; near East Rookery; and near **Tolstoi** Point. Currently only the site on Walrus Island is an active rookery. **Kenyon** (1962) noted that the **haulout** site near Northeast Point on St. Paul Island was formerly the largest rookery in the **Pribilof** Islands, however, no pups have been seen there since 1957, which is about when major declines in the numbers of northern sea lions apparently began.

The ultimate causes of the decline in the northern sea lion population in Alaska are unknown (**Merrick** et al. 1987). However, it has been postulated that disease (possibly *Leptospira*), changes in prey resources, increased mortality through shooting, and possible entanglement in nets and other debris may all be contributing factors.

Some evidence suggests that changes in the quantity and size of walleye **pollock** (*Theragra chalcogramma*), the principal prey of northern sea lions, may be a factor in their decline (**Bakkala** et al. 1987; **Fowler** In press; **Loughlin** 1987; **Frost** and **Lowry** 1986). It is also possible that increased mortality of pups that become separated from their mothers during some types of censuses at rookeries (**Lewis** 1987) may be a factor contributing to the decline. Away from the **haulout** sites, there is little evidence that noise from either airborne or underwater sources has serious detrimental effects on northern sea lions. In fact, some studies show that sea lions habituate well to some severe forms of noise (**Shaughnessy** et al. 1981, **Mate** and **Harvey** 1987).

Harbor Seal

Harbor seals are distributed throughout the portion of the study area south of Nunivak and the **Pribilof** islands. Harbor seals do not necessarily aggregate at large rookeries to breed, pup and suckle their young. Aside from the resident population on Otter Island in the **Pribilofs**, most harbor seals in the northern part of the study area probably move south (away from advancing ice) during winter. Of the 41 terrestrial **haulout** sites considered in detail in our study area, only about 6-8 appear to have consistently supported large fractions of the total eastern Bering **Sea** population of this species--most of these important sites are on the Alaska Peninsula.

Harbor seals respond to noise and human disturbance in a variety of ways. In some situations it is not possible to disperse them even using severe forms of disturbance; *i.e.*, they appear to accommodate to noise and disturbance in some instances when they are actively feeding. However, there have been instances where human disturbance at harbor **seal haulout** sites have caused the sites to be abandoned and pups to be separated from their **mothers**, thereby causing mortality (Johnson 1977; see 'Results' section for details). Thus, our evaluation of the importance and vulnerability of harbor seals at 41 terrestrial **haulout** sites has been influenced by the fact that abandonment of sites and consequent mortality of pups has been shown to be associated with some kinds of noise and disturbance near such *sites*. Based on **all** criteria considered in this study, including the general susceptibility of this species, and the susceptibility of the 41 **haulout** sites to disturbance we determined that the sites in **Izembek/Moffet** Lagoon, Port **Heiden**, Port **Moller**, Cinder River, Seal Islands and **Ilnik** (**all** on the Alaska Peninsula), and in Nanvak Bay near Cape Peirce, Ugashik Bay, and on Otter Island in the **Pribilofs** to be the most important and potentially most vulnerable to noise and disturbance associated with **OCS** development (**Table 10**).

The number of harbor seals recorded at **haulout** sites in the Bering Sea, especially at some sites in the southeastern Bering **Sea**, has apparently declined dramatically during the recent decade (Pitcher **1986**). Although several reasons have been given for the apparent recent decline of harbor seals (e.g., disease, over-exploitation in earlier years, increased predation, increased fouling in fishing **gear**, reductions **in** principal prey [**walleye pollock**]), none of these suggestions have been clearly documented. At present, the sites that appear to have been most significantly reduced in size (fewer seals counted recently) are the Seal Islands, Cinder River, and **Izembek/Moffet** Lagoon, on the Alaska Peninsula. However, as noted in the 'Results', counts at any one of these sites may be greatly influenced by such factors as the time of day, time of year, tide, weather, availability of prey, etc. Recommended programs designed to more carefully monitor the number of harbor seals at **haulout** sites **in** Bristol Bay could provide more of the data needed to determine the status of this species in the study area, prior to **OCS** development (Hoover **1988b**).

Max. Count is from either "1980'a" or "Curr. Est." columns (whichever is greater) in Table 6.

Mean Max. Count is from "190s", "1970's", "1980s" and "Cur. Est." columns in Table 6.

Proportion of Population is calculated from "Curr. Est." column in Table 6.

Age/Sex Composition x Activity values are based on whether age/sex classes are present and whether pupping occurs regularly at or near the site (all=0.5, Ad. only=1), and the number of different locations where harbor seals haul out (1=many, 2=several, 3=few) associated with the site.

Duration of Use is based on the approximate proportion of the year that the site is used.

Consistency of Use categories are as follows: 1=annual and relatively consistent, and 2=inconsistent.

Site Characteristics values were based on topography and proximity to noise/disturb. source near the haulout site (1=any site near noise/diatomb., 2=cliffs, 3=bluffs/slopes, 4=low or no relief).

Species Characteristics values were assigned based on the sensitivity of the species and associated potential for mortality as a result of disturbance (1=high, 2=medium, 3=low).

Pacific Walrus

Only male Pacific walruses haul out at terrestrial sites in the southern part of the study area, *i.e.*, at island and mainland *sites* south of the St. Matthew-Hall Islands area (south of about 60°N). During **fall**, as the pack-ice advances south through Bering Strait, females with calves return to the northern part of the study area, where they are joined by **males** that have moved northward from southern sites. **Haulout sites on St. Lawrence Island** and on the nearby **Punuk Islands** are particularly important at this time of year (autumn); all age and sex classes may be found **hauled** out at these terrestrial sites in some years. Breeding occurs on the pack-ice **in** late winter-early spring and calves are born on the ice **in** spring, Females and newborn calves remain with the pack-ice as **it** retreats north out of the study area in early summer, whereas many males remain south and **utilize haulout** sites in Bristol Bay.

There is only a relatively **small** body of information concerning the effects on walruses of various kinds of noise and disturbance **however**, some of **this** information is particularly relevant to this study. **In** general, walruses respond to noise and human disturbance by temporarily leaving the **haulout** site; **if** the disturbance persists, the site may be abandoned (**Fay et al. 1986**; for more details see 'RESULTS'). Natural mass mortality of walruses has occurred at a **Punuk Island haulout** site in at **least** one year, **1978** (Fay and **Kelly** 1980). Although it is unclear how mortality of this type has occurred, it does indicate **the** magnitude of such mortality (many hundreds of animals died) that can occur when large numbers **of** animals (tens of thousands) are hauled out at one site. At other sites (Cape Peirce), shooting and other types of harassment such as by aircraft and boats have caused severe disturbances.

Based on all criteria considered in this study, including the general susceptibility of this **species**, and the susceptibility of the **31 haulout** sites to disturbance, we determined that the sites at **(1)** Port **Moller** and Cape Seniavin in southern Bristol Bay, **(2)** at Round Island, Cape Peirce and Cape **Newenham** in northern Bristol Bay, and **(3)** at St. Matthew and Hall islands,

King Island, eastern St. Lawrence Island and North **Punuk** Island in the central and northern Bering Sea rate high in our **IPSI** evaluation scheme (Table 11).

Both the Amak Island and Cape Seniavin **haulout** sites have been disturbed in recent years by fishing boats and low-flying aircraft and beachcombers landing at the site; poachers have also frequently disturbed the Cape Seniavin site (**J.J. Burns, pers. comm. 1988**). It is probable that many of the walrus recorded in the Port **Moller** area have been displaced (through disturbance) from nearby Cape Seniavin (details given earlier in 'Results'). Further, there is evidence that walrus using the Cape Seniavin site are also associated with the Round Island site in northern Bristol Bay. At least one **male** walrus tagged at Round Island was recovered (dead) on the beach at Cape Seniavin.

The Cape Peirce **haulout** site has been reoccupied since the early 1980's. Significant numbers hauled out at this site in 1983, but shooting and other disturbances prevented a sustained **reoccupancy** that year (D. Fisher, USFWS, **pers. comm. 1988**). Large numbers of walrus (about 4,000-6,000 males) again reoccupied this site in 1984. Very large numbers of walrus (12,000 males) have been recorded at Cape Peirce in recent years, even though shooting of some animals has occurred at this site every year since 1986 (D. Fisher, **USFWS, pers. comm. 1988**). Daily surveillance at Cape Peirce during the summer haulout period began in 1984 and currently there is careful documentation of hunting and other disturbances.

Max. Count is from either "1980s" or "Curr. Est." columns (whichever is greater) in Table 7

Mean Max. Count is from "1960's", "1970's", "1980's" and "Cum. Est." columns in Table 7.

Proportion of Population is calculated from "Curr. Est." column in Table 7.

Age/Sex Competition x Activity values are based on whether all age/sex classes are present at the site (all=0.5, ad. males only=1), and the number of different locations at the site where walrus haul out (1=many, 2=several, 3, few).

Duration of Use is the approximate proportion of the year that the site is occupied.

Consistency of Use categories are as follows: 1 = annual and consistent, and 2. inconsistent.

Site characteristic values were based on topography and proximity to noise/disturb. near the haulout site (1 = any site near noise/disturb., 2 = cliffs, 3 = bluffs/slopes, 4 = low or no relief).

Species Characteristics values were assigned based on the degree of sensitivity of the species and associated potential for mortality as a result of noise/disturbance (high=1, medium=2, low=3).

* An asterisk indicates that this haulout site is occupied mostly by adult males. All other haulout sites (those without asterisks) are occupied by male and female adults, subadults and calves.

SUMMARY AND CONCLUSIONS

The following summary and concluding remarks are presented in relation to the four broadly defined **OCS** Planning Areas (Norton Basin, St. Matthew-Hall, North Aleutian Basin, and St. George Basin) in our study area (see Fig. 1). Each of these four planning areas contain **haulout** sites that are important to more than one of the pinniped species considered in this report. Many of these sites ranked high in our Inter-site Population Sensitivity Index (**IPSI**) evaluations.

Norton Basin Planning Area

There are 14 **haulout** sites in the Norton Basin Planning Area used by two of the four species of pinnipeds considered in this study; no northern fur seals or harbor seals haul out in significant numbers in this planning area. However, 86% (12) of the 14 sites in this planning area are used by one species, the Pacific walrus (Fig. 12). Two (14%) of these **haulout** sites, the one on North **Punuk** Island, and the one on King Island had high **IPSI** ratings (see Table 11). Northern sea lions have occasionally hauled out at Southwest Cape on St. Lawrence **Island** and on South Punuk Island; however, there is no current information concerning the use of these sites by this species, consequently, there was insufficient information to assign an **IPSI** value (compare *Table 5 with Table 9*).

St. Matthew-Hall Planning Area

In the St. Matthew-Hall OCS Planning Area 24 **haulout** sites have been used by three of the four pinniped species considered in this study; there are no northern fur seal **haulout** sites. The majority of the sites are used by northern sea lions (11 sites, 46%); however none of these 11 sites ranked high in the overall evaluation of importance or **potential vulnerability** (Table 9). Pacific walrus sites were second in abundance (8 sites; 33%) and four of these, all on St. Matthew or Hall islands, ranked high in our **IPSI** rating system (Table 11). Harbor seal sites were least abundant (5 sites; 21%) in this planning area. Nevertheless, the site(s) in Kuskokwim Bay had relatively high **IPSI** values (Table 10); this area , and the areas to the east near Avinof

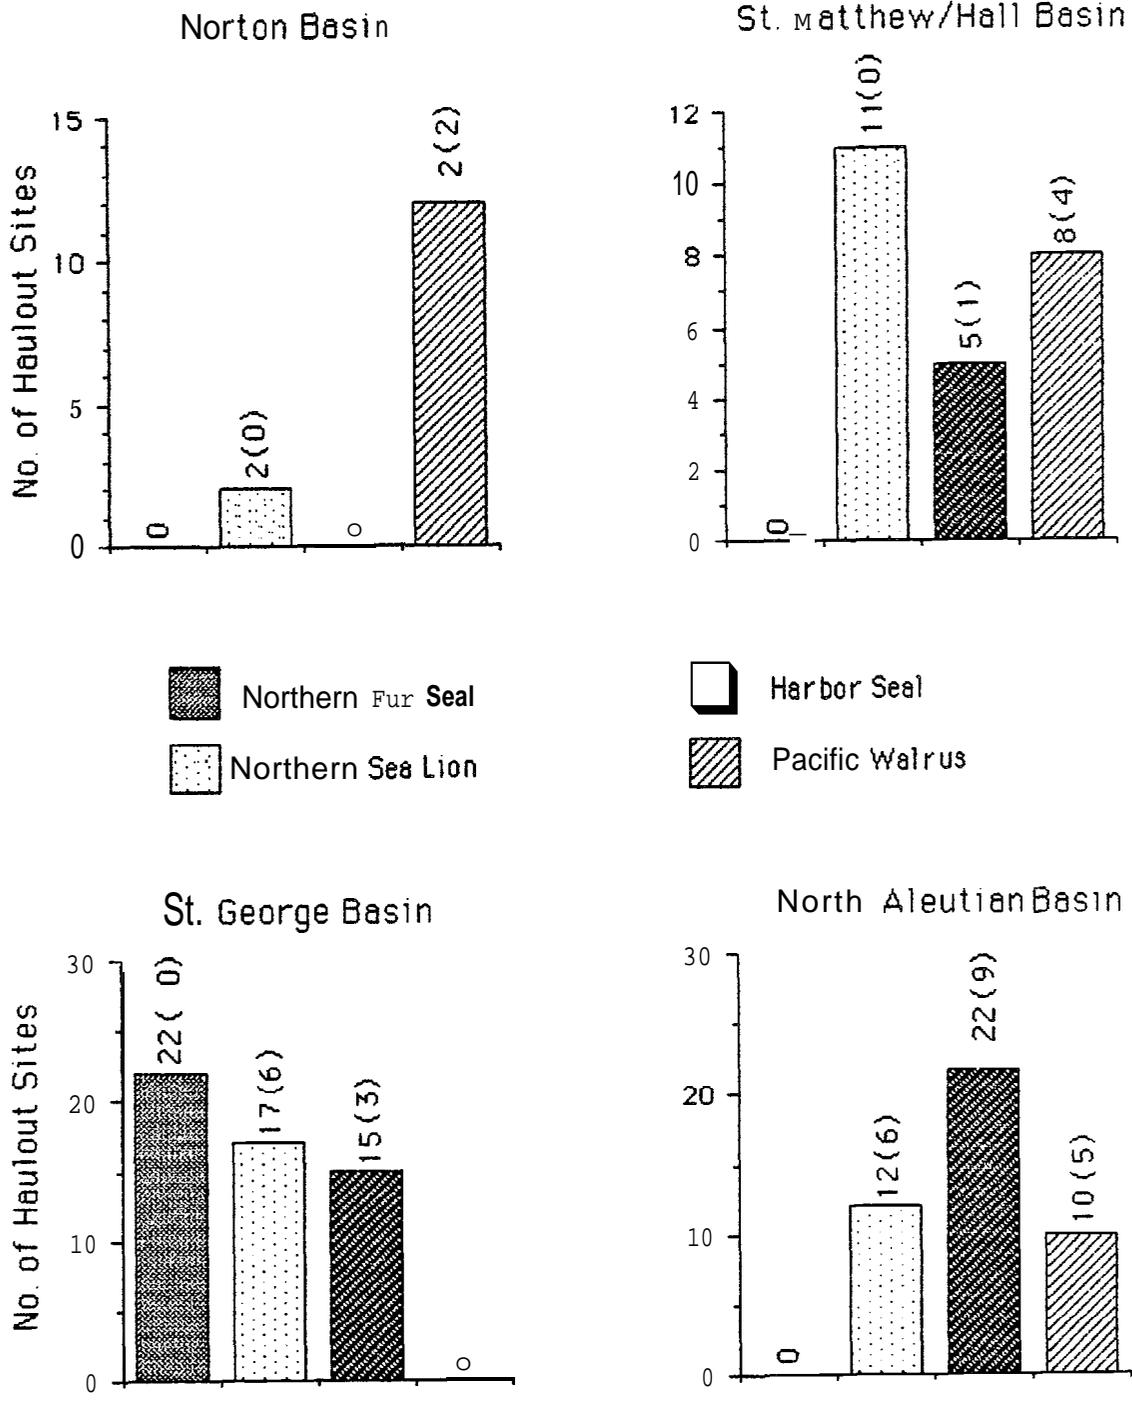

Figure 12. Summary of haulout sites in various OCS Planning Areas in the Bering Sea, Alaska. The number of sites that rated high in our IPSE evaluations are shown in parentheses.

Pt., may be the most northerly major harbor seal pupping areas in the eastern Bering Sea, and probably this is the least studied harbor seal habitat in the study area.

North Aleutian Basin Planning Area

The North Aleutian Basin Planning Area contains 44 haulout sites used by three of the four pinniped species considered in this study (Fig. 12). Harbor seals use 22 (50%) of these sites including 9 of the 13 sites that had the highest IPSI ratings for harbor seals in this study (see Table 10). Twelve (27%) sites were occupied by northern sea lions, and at least six (14%) of these sites had high IPSI ratings. Ten sites (23%) in the North Aleutian Planning Area are occupied by Pacific walrus; five (11%) of these sites had very high IPSI values (Table 11).

St. George Basin Planning Area

The St. George Basin Planning Area supports the largest number of haulout sites for the species considered in this study--a total of at least 54 sites for three species. There are no consistently used Pacific walrus haulout sites in the St. George Basin Planning Area. On the other hand, all 22 (100%) of the northern fur seal haulout sites in the eastern Bering Sea are in this planning area (Pribilof Islands and Bogoslof Island); these 22 sites represent about 40% of the total 54 sites used by the four species studied in this planning area (Table 10). Seventeen sites (32%) in this planning area are occupied by northern sea lions, and 6 (11%) of these had high IPSI ratings (Table 9). It was not possible for some sites to be evaluated (compare Table 5 with Table 9) because there was insufficient information on their current use. At least 15 sites (28%) in the St. George Basin Planning Area are used by harbor seals, and three (6%) of these sites (two in the Fox Islands and Otter Island) had very high IPSI ratings.

It should be remembered that we have not discussed rookeries/haulouts used by very small numbers of pinnipeds. With the exception of northern fur seals (which use only the Pribilofs and Bogoslof Island), hundreds of such sites are used by small groups (1-10 individuals) of Pacific walruses,

northern sea lions, and especially harbor seals. The degree of fidelity to specific haulout sites (from greatest to least) by the four species we studied are: northern fur seal, walrus, northern sea lion and harbor seal. The last two species are most likely to haul out at sites not considered significant (far less than 1% of the study area population) and not considered in this study. This is especially true for harbor seals which are ubiquitous in most of the study area and haulout at hundreds of sites not considered here.

In summary, we evaluated 120 of 136 major terrestrial haulout sites in four different OCS Planning Areas to determine their overall importance and potential vulnerability i.e. their sensitivity to possible OCS activities. It was not possible to evaluate some sites mentioned in the text and tables because of insufficient information on the number of animals currently using the sites and uncertainty about the consistency of use of the sites. Of the 44 sites in the North Aleutian Basin Planning Area, almost half (20 sites; 45%) were ranked high in our IPSI evaluations; this number represents almost half of the total 41 most highly rated sites for all four species in the study area. Of the 54 sites in the St. George Basin Planning Area, 19 (35%) were rated high; this number is strongly influenced by the 10 most highly rated northern fur seal sites on the Pribilof Islands. Of the 24 sites in the St. Matthew-Hall Planning Area, 5 (21%) were ranked high in our IPSI evaluations, and most (4 of 5; 80%) were sites occupied by Pacific walrus. Similarly, of the 14 sites in the Norton Basin Planning Area, only 2 were rated high in our IPSI evaluations; both of these sites were occupied by Pacific walrus.

APPENDICES

Appendix 1 gives details of an investigation of the acoustic environment at eight representative **pinniped haulout** sites in the eastern Bering Sea. Two sites were selected for each of the four pinniped species; sites were selected on the basis of their importance and vulnerability and the extent to which they represent different characteristics.

Appendices 2 through 5 give detailed descriptions and show locations of each major **haulout** site for the four species of pinnipeds considered in this study. Most descriptions are based (1) on information provided in the literature (e.g., Jordan and Clark 1898), (2) from available topographic maps, (3) from resource agency habitat maps (e.g., **Sowls et al.** 1978; ADFG 1973), (4) from NOAA **hydrographic** charts. Bathymetric and topographic information in the text and on the maps are approximate and should by no means be used for navigational purposes.

Appendices 6 through 8 provide detailed tabulations of all available information concerning the number of northern sea lions, harbor seals and Pacific walrus hauled out at different times **at** various sites in the study area. Most of the detailed information in Appendices 6-8 is not provided elsewhere in the report, but it has been used to produce the summary tables given in the 'Results' section of this report. We have not tabulated the masses of northern fur seal data collected over the last century in the **Pribilof** Islands area; virtually all of this information is available in the form of technical reports from the National Marine Mammal Laboratory, Seattle, WA.

**APPENDIX 1. ANALYSIS OF ACOUSTIC ENVIRONMENT OF SELECTED
PINNIPED HAULOUT SITES IN THE ALASKAN BERING SEA**

INTRODUCTION

This investigation examines **aspects** of the acoustic environment at eight major pinniped **haulout** sites in the Alaskan Bering Sea. These sites are:

1. **Sivutch** on the south coast of **St. Paul** Island; northern fur **seal**.
2. **Polovina** on the east coast of **St. Paul** Island; northern fur **seal**.
3. **Zapadni** on the southwest coast of **St. George** Island; northern sea **lion**.
4. **Ugamak** Island (SE end) south of **Unimak** Pass; northern sea **lion**.
5. **Port Moller** on the north shore of the Alaska **Peninsula**; harbor **seal**.
6. **Otter Island** south of **St. Paul** Island; harbor **seal**.
7. **Cape Peirce** in northern **Bristol** Bay; **Pacific** walrus.
8. **Cape Seniavin** NE of **Port Moller**; **Pacific** walrus.

The aspects of **the** acoustic environment that were studied are:

Ambient Noise - Both airborne and underwater noise characteristics

Industrial Noise Source Characteristics - Aircraft, small-craft, fishing trawlers and commercial cargo traffic

Sound Transmission Loss - Airborne, underwater, and transmission through the water surface

The ambient noise characteristics for the sites were estimated using data obtained from studies of similar areas. The noise source characteristics were obtained from data reported in the literature and from BBN archives. Transmission loss characteristics for airborne and underwater sound were estimated using standard analytical procedures and computer models. An **analytical** procedure was developed for prediction of **transmission** of sound from aircraft **into** shallow water, **since** an existing procedure **was** not available. Procedures are **described** for using the information **obtained** in this

study to predict noise exposure levels and develop zone-of-influence determinations for the various species of concern in this project.

RESULTS AND DISCUSSION

Ambient Noise Characteristics

Pinniped haulout sites are influenced by both underwater and airborne ambient noise. In the area near the beach, surf noise is the dominant contributor. The overall airborne noise level and spectrum shape are related not only to the local wind speed but also to the height of the swell which may be influenced by distant storms at sea. Beyond 100 to 200 m offshore the airborne noise level is influenced primarily by **local** breaking wave crests and may become quite low during **calm** sea conditions. Some surf noise data reported for moderate wind speed conditions (about 10 kts) are shown in Fig. 1¹. The surf noise spectra reported for two different areas can be seen to be similar except at 50 Hz where the BBN data show a considerably higher level. This may be the result of higher swell conditions (swell height was not reported). The spectrum labeled "offshore" was measured for the same sea conditions as the surf noise spectrum but at a point about 200 m from the beach. The sea state was given as "choppy with some breaking crests". The band levels shown for the offshore spectrum correspond to those measured on land in rural areas and thus represent relatively quiet airborne noise conditions.

Several sources of data are available for ambient noise in shallow water. Wenz (1962) has compiled data from several shallow water regions. An example spectrum is shown in Fig. 2 for water depths less than 40 m and a wind speed of about 10 kt. The area had some contribution at low frequencies from distant shipping, producing a spectrum peak at 100 Hz. Data reported by Malme et al. (1986) for measurements near St. Lawrence Island in water depths of 12 m are also shown in Fig. 2. The wind speed during these measurements was about 10

¹ It is customary to use 20 μPa as the reference for airborne sound levels since this results in a 0 dB sound pressure level for the normal human minimum threshold of hearing. We will use the underwater sound reference level of 1 μPa in this report for both airborne and underwater sound to avoid confusion and simplify spectrum comparisons.

AIRBORNE AMBIENT NOISE IWAR 13 EACH AREAS

1/3 Octave Band Spectra

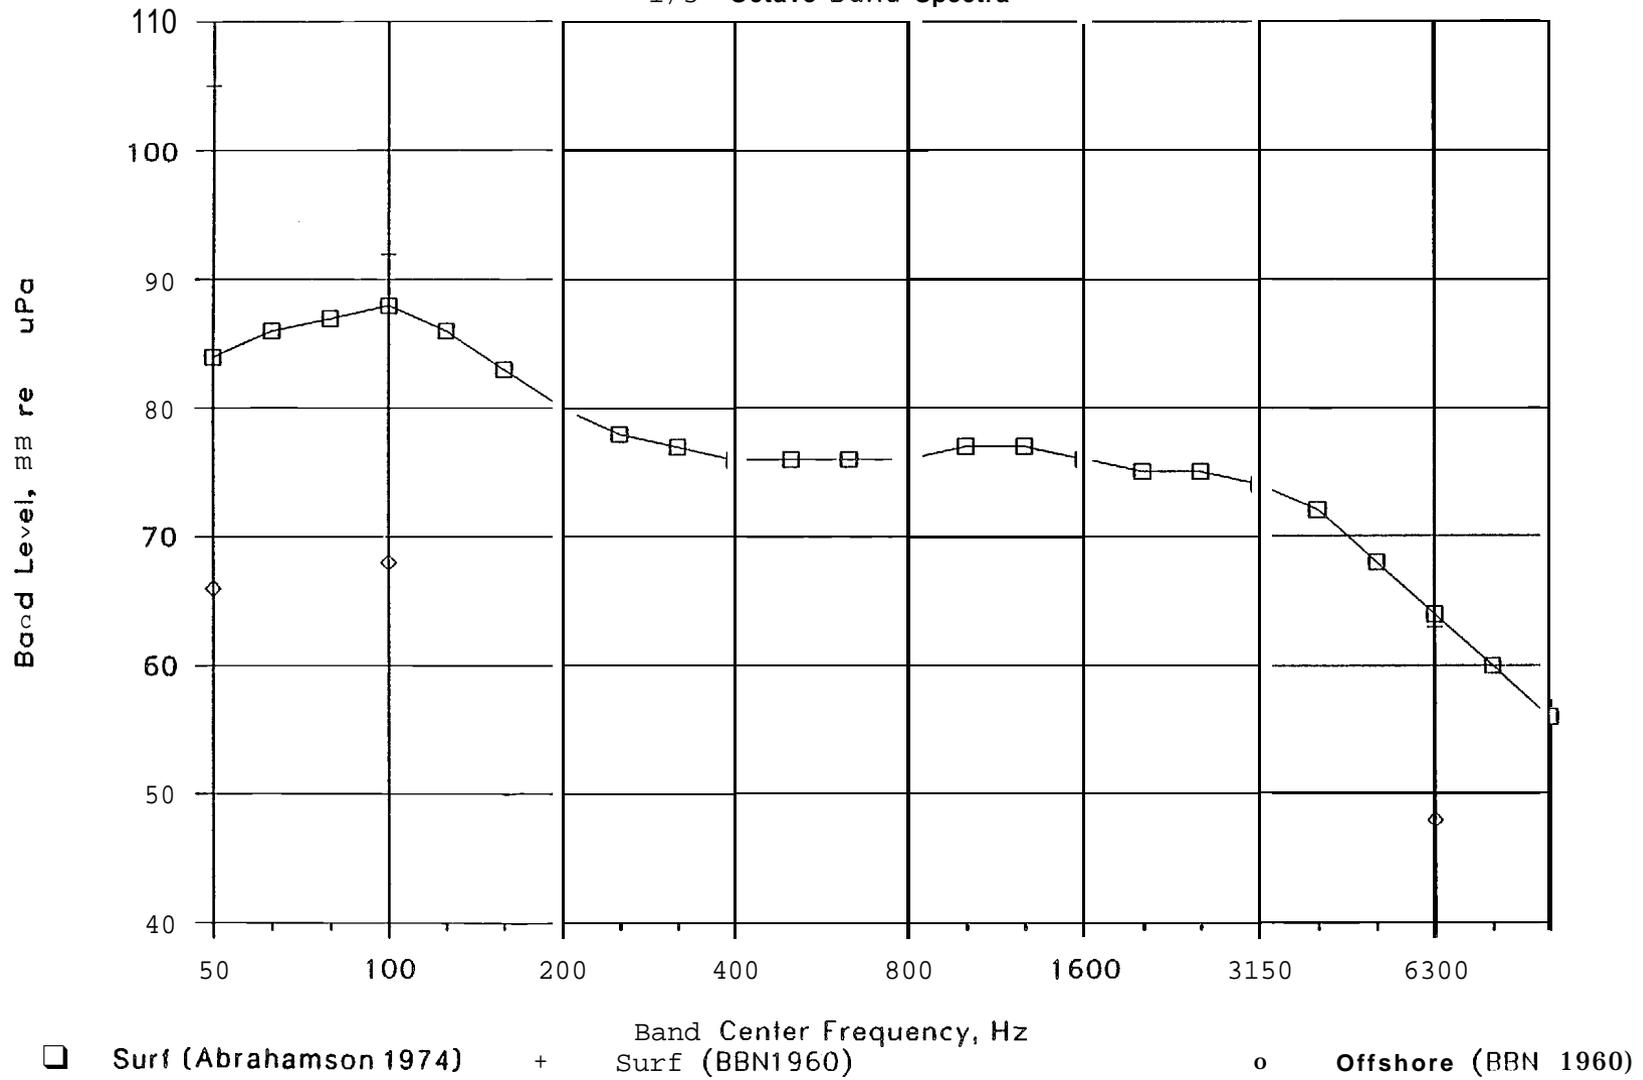

Figure 1. Airborne ambient noise near beach areas.

SHALLOW WATER AMBIENT NOISE

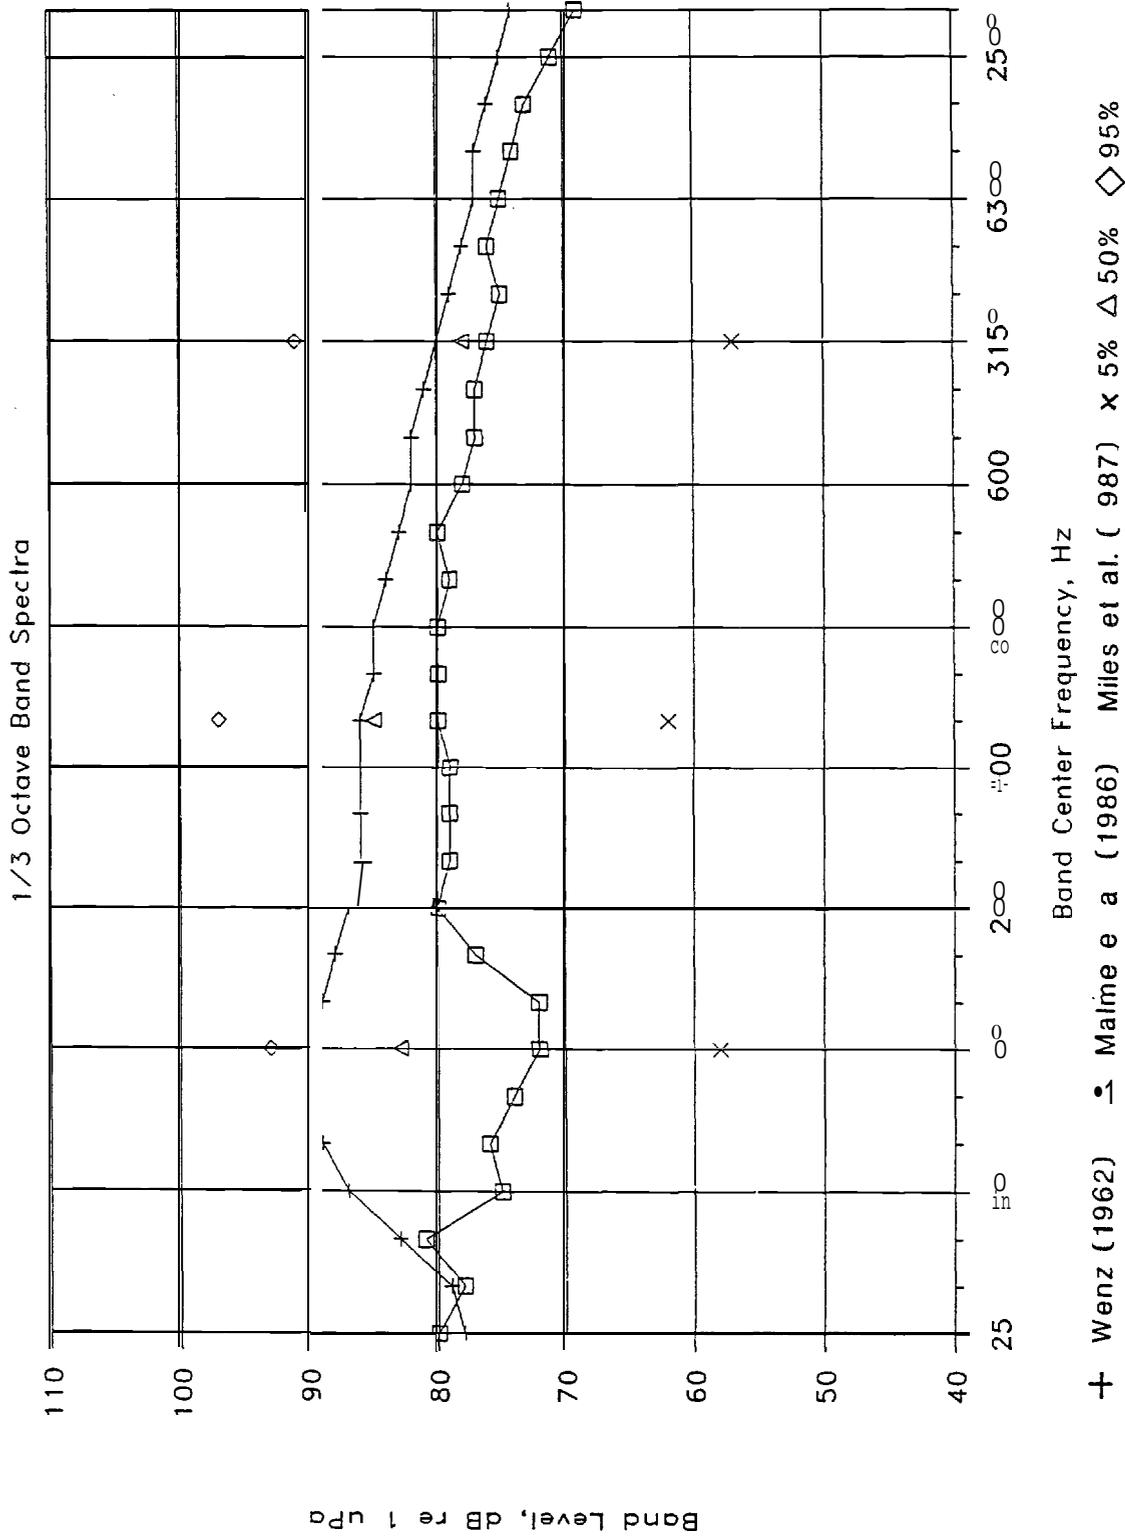

Figure 2. Shallow water ambient noise.

kt . **Distant shipping did** not evidently influence the ambient spectrum during **this** measurement **since** the levels at low frequencies do not show any **increase** over those at **mid-band**. No data were found for underwater **ambient noise levels** near the surf zone; however, at low frequencies **in** very shallow water the **levels** underwater are expected to be **similar** to those **in air**. **This will be** shown by an **analysis** presented **in** the **section** on Transmission Loss (p.103).

The range of underwater ambient **noise** levels expected **in** shallow water where **shipping noise is** not an **important factor** is indicated in the figure by the percentile spectra. These spectra are based on data and estimates obtained for shallow (15 m) Beaufort Sea regions by Miles et **al.** (1987). The percentile **levels** shown would be expected to be relevant also for Bering Sea regions where shipping noise is not significant. However, for the **Ugamak** Island site near Unimak Pass shipping would be expected to contribute a moderate peak near 100 **Hz** similar to that shown in the Wenz spectrum.

Industrial Noise Source Characteristics

At the study sites selected, single-engine and twin-engine aircraft, helicopters, small-craft, fishing vessels and commercial **cargo vessels are** expected to be the dominant types of industrial noise sources. These sources are **all** mobile and contribute noise to a pinned **haulout** site over a time interval related to their speed and distance from the site. **A small** aircraft traveling at a **low** altitude will produce high **levels** for a relatively short period of time at a point on the ground under *its* flight path, whereas a large aircraft traveling at a high altitude may produce comparable levels for **a** longer period of time. The rate of increase in noise **level** on the ground is less abrupt for the large aircraft but the noise remains at high **level** for a longer period of time. Thus both startle and avoidance types of reactions may occur for aircraft overflights near **haulout** areas. Similar reactions may occur when high speed boats and **larger** cargo vessels pass near areas where animals are engaged in underwater activity. Most of the time the majority of the animals at a **haulout** site are out of the water so aircraft noise is potentially more **likely** to cause disturbance than boat traffic.

Information on the acoustic output of aircraft and vessels that may pass by the study sites is presented in the form of standardized 1/3 octave spectra to facilitate comparison of the noise levels produced by the various sources and provide source level spectra needed for estimating the noise exposure at various ranges. It is customary to present aircraft noise spectra as measured for an overflight at a reference altitude of 1000 ft (300 m) rather than a reference distance of 1 m as is usual for underwater sources. This is done because of the strong dependence of atmospheric absorption at high frequencies on temperature and humidity conditions. If aircraft radiated noise spectra were required to be corrected to a reference distance of 1 m it would be necessary to have very accurate measurements of temperature and humidity as a function of altitude in order to minimize errors in the corrected source level spectrum. Since most applications of radiated noise data are for predictions of levels at slant ranges of 300 m or greater, it is not necessary to correct measured levels to a reference distance of 1 m. Instead, flyover data are generally corrected to represent the received noise level on the ground for an overflight at 300 m altitude for "Standard Day" conditions of 15°C and 70% relative humidity.

Aircraft Noise Spectra

Figure 3 shows 1/3 Octave radiated noise data for representative 1-engine and 2-engine propeller and turboprop aircraft. These data were obtained from overflights of Cessna 172, Piper Archer, Piper Navaho, Beech Baron, and Gulf stream Commander types of aircraft. Figure 3A presents data for a take-off power setting and Fig. 3B presents data for an approach power setting. (Note the 10 dB difference in band level between the two figures.) The 2-engine turboprop aircraft can be seen to be noisier than the two types of piston engine aircraft, however it is also the largest of the types represented in these data.

Radiated noise data for helicopters are presented in Fig. 4. Data are presented for those craft which might be expected to fly near the study sites such as the Bell 206B, 205, and 222 and the Sikorsky 61 (similar to the Hughes 369D). Figure 4A presents spectra for cruise and takeoff conditions. Spectra for loaded and approach power settings are shown in Fig. 4B. The Bell 205 can

Loaded and Approach Power, 300 m Alt.

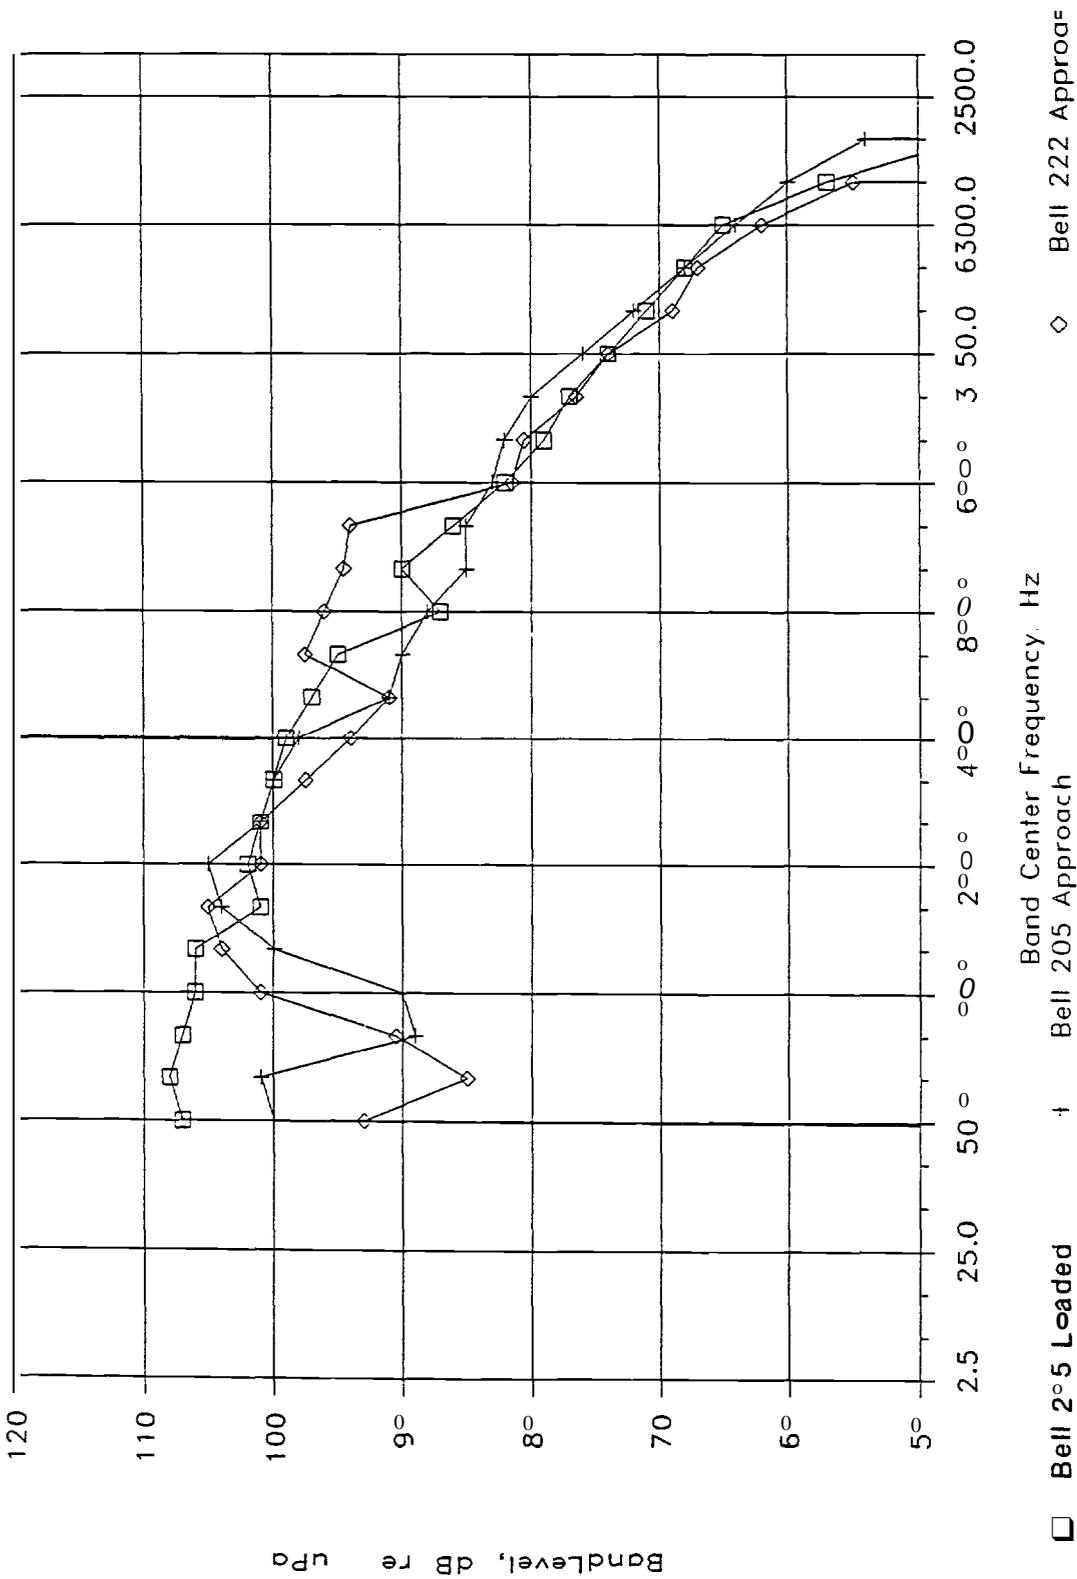

Figure 4B.

be seen to produce the highest noise levels for **both** conditions. If the radiated noise data for the helicopters are compared with the data for the fixed wing aircraft (Fig. 3) the 1-engine and 2-engine aircraft considered here can be seen to be louder than the helicopters (except the **Bell 205**) during takeoff. However, during approach the helicopters are comparable to the 2-engine aircraft. Both *are* considerably noisier than the 1-engine aircraft (**Cessna 172**). If the maximum band levels at low frequencies for the **Bell 205** and the 2-engine turbojet were corrected to an equivalent 1 m source level corresponding to underwater source **procedure, levels of about 160 dB** would be obtained.

Small Craft and Commercial Vessel Noise Spectra

Underwater radiated noise data for **small** craft are shown in Fig. 5A. These data from **Malme et al.** (1982) are based on measurements during full power operation of a 20 HP outboard motor on a 13 ft (4 m) "Boston Whaler" and a 16 ft (5 m) inflatable "Zodiac". The 24 ft (7.5 m) **outdrive** was powered by twin 80 HP engines and the spectrum shown represents **full** power operation. Underwater radiated noise spectra from larger vessels are presented in Fig. **5B**. If the spectrum for the 65 ft (20 m) twin diesel **vessel** is compared with the spectra shown in Fig. 5A for the outboard powered boats, the twin diesel operating at 10 kts can be seen to be quieter than the outboards at full power and very much quieter than the twin **outdrive**. The spectra shown in Fig. 5B for the tug and barge and for the fishing trawler are representative of noise produced by medium-sized cargo vessels with **fully** cavitating propellers. During these conditions the narrow band noise components produced at low frequencies by engine and machinery operation are often overwhelmed by the broadband high frequency noise of cavitation bubbles. The tug and trawler represent vessels in the 2000 HP range which probably are the largest type of commercial vessel operating near shore in pinniped **haulout** areas. The maximum band levels at 1 m for the radiated noise from these vessels can be seen to be about 160 dB. This was **also** the maximum low frequency band level produced by the larger aircraft considered in this study.

Transmission Loss

A discussion of the transmission of airborne sound is presented first since aircraft are the most probable source of industrial noise near haulout areas. This is followed by a discussion of underwater sound transmission and transmission of sound through the water surface.

Sound Transmission in the Atmosphere

Sound transmission from a source in an unbounded atmosphere is attenuated only by geometrical spreading of the sound energy and by absorption of sound energy by air molecules. Sound transmission from a source near a non-rigid or permeable boundary is also influenced by reflection and refraction losses and by wave transmission along the boundary surface. Fortunately the most significant sound transmission from an aircraft to a point on the ground involves a direct path from the source to receiver which is elevated well above the refracting and scattering effects of near-surface transmission. Because of this, it is necessary to consider only spherical spreading, atmospheric absorption, and ground reflection effects in the transmission loss (TL) equation for estimating the received level on the ground from an aircraft passing nearby. The relationship can be stated as:

$$L_r = L_s - 20 \text{ Log}(R) - a R + R_g \text{ dB re } 1 \text{ } \mu\text{Pa} \quad (1)$$

where: L_r = Received level spectrum near the ground
 L_s = Source Level spectrum at 1 m from the source
 R = Slant range in m
 a = Atmospheric absorption spectrum in dB/m
 R_g = Ground reflection spectrum, dB

Since for most aircraft noise transmission calculations, a reference sound level at 300 m is used rather than a 1 m source level, Eqn (1) can be rewritten as:

$$L_r = L_{ref} - 20 \text{ Log} (R/R_{ref}) - a R + a(SD) R_{ref} \quad (2)$$

where: L_{ref} = Reference source spectrum at 300 m for standard day conditions
 R_{ref} = 300 m
 $a(SD)$ = Atmospheric absorption spectrum for standard day conditions

The procedure for measuring **Lref** utilizes microphones near the ground so the ground reflection effect is included in the measured level. **Equation (2)** is to be applied successively **to** each spectrum band in calculation of **the Lr** spectrum; i.e., the 50 Hz band **level** of the Lref spectrum would be used with the 50 Hz band levels of the absorption spectra to determine the 50 Hz band level of **Lr**, etc. Since the spreading loss term is not frequency dependent, it is calculated once and used repeatedly.

Atmospheric absorption **at** low frequencies below 30 **kHz** is produced by molecular absorption by oxygen and nitrogen molecules. The amount of absorption is dependent on frequency, temperature, relative **humidity**, and to a small degree on atmospheric pressure. The **physical** relationship between these parameters **is not easily** expressed **in** mathematical relationships but an **empirical** computer algorithm has been developed for closed-form **calculation** of absorption coefficients from **input** of the four atmospheric parameters (**ANSI S1.26-1978**). Examination of the climatic atlas data showing temperature and humidity **values** for the Bering Sea region of interest to *this* study during the **pinniped haulout** season disclosed that the expected range of variation was not large. A table of absorption coefficients was prepared using excerpts from the ANSI Standard. The results are shown in **Table 1** which presents atmospheric absorption coefficients estimated for spring and summer conditions in the study areas. Values are presented showing attenuation per 100 m. Attenuation values at 150 m (500 ft) are also given to facilitate correction of reference spectra to 150 m and 450 m altitudes. For flyovers at 300 m the corrections to the standard day conditions can be used to estimate aircraft noise spectra at the Bering Sea sites.

Underwater Sound Transmission

In unbounded deep water sound transmission characteristics are determined by geometric spreading loss and molecular absorption of the sound energy in the same manner as in atmospheric transmission. Molecular absorption losses are much less underwater, however, and are not significant for frequencies less than 5 kHz and ranges less than 5 km. Sound transmission in shallow water is influenced by reflection losses from the bottom and surface, refraction from sound speed gradients, refraction from sub-bottom layers, and scattering

from rough surfaces. All these effects must **be** considered **along** with geometric spreading loss to obtain estimates of the received level at some distance from a source. In the present study, sound transmission is further modified **by** the bottom **slope** present in most beach **areas**. When sound is transmitted **upslope**, as is the case for a source passing near a **haulout area**, two effects occur. If the bottom reflection loss is **low**, sound levels tend to be higher than those predicted by geometric spreading because the sound energy becomes concentrated in a smaller water volume as it travels **upslope**. However, if bottom loss is high, sound levels are reduced at a greater rate than expected from geometric spreading since sound undergoes more bottom contact than would occur for transmission over a constant depth bottom. These effects are further complicated by sound transmission and refraction in bottom material which often is an important means of sound transmission in very shallow **water**.

For a **rigid**, impermeable bottom theory predicts that sound transmission is not possible at frequencies for which the depth of water is less than $1/4$ wavelength. Thus for sound transmission **upslope** from a broadband source, the **low** frequencies **will** be cut off **or** attenuated heavily at shorter ranges than the high frequencies. However, since most bottom material is not rigid and impermeable, this *frequency-selective* cutoff *characteristic is not* always observed. **The** presence of water-saturated sediments often permits significant sound transmission to occur up into the surf zone.

The **haulout** sites selected for this study have several types of bottom material as well as differences in bottom slopes. After examining the charted depths near these sites and reviewing information about bottom conditions we were able to divide the 8 sites into two general categories based on bottom composition and beach slope as follows:

<u>Site</u>	<u>Slope</u>	<u>Bottom Composition</u>
Port Moller	-0.003	silt and sand
Cape Seniavin	-0.0045	silt and sand
Cape Peirce	-0.0036	sand and rock
Ugamak Island	-0.09	sand and rock
Sivutch (St. Paul)	-0.01	rocky
Polovina (St. Paul)	-0.009	rocky
Zapadni (St. George)	-0.01	rocky
Otter Island	-0.012	rocky

Ugamak Island was considered as a special case since it has a steeper beach than the other sites.

Sound Propagation Modeling

The most appropriate type of sound propagation model to use for prediction of transmission characteristics at these sites is a model based on a solution of the parabolic wave equation for acoustic waves in a range-dependent medium. This type of model can accommodate changes in transmission properties with range such as sloping bottoms and variations in sound speed profiles and bottom layer materials. It also develops a solution for the sound field as a function of depth and is appropriate for sound transmission from a shallow source to a shallow receiver - as required by this study. The depth-averaged type of transmission models such as the Weston/Smith model (Miles et al. 1987) are not appropriate for shallow source - shallow receiver transmission and do not provide for sound transmission in bottom layers (unless special modifications are made to the input parameters). Fortunately a model based on an implicit finite difference solution of the parabolic wave equation has become available. This "IFD Model" was developed by Lee and Botseas (1982) at the U.S. Naval Underwater Systems center, New London. It has been adapted to run on IBM AT compatible computers and was used for the modeling required by this study.

The geometry used for the model in this study is shown in Fig. 6. This geometry features a beach profile which has a constant slope connecting a flat region offshore with a small flat region near shore. There are also two sloping bottom layers which have range-dependent thickness. To represent transmission from smaller vessels to pinnipeds swimming in the surf zone, a source depth of 1 m and an average receiver depth of 2 m was used. In shallow water with a sloping bottom the transmission characteristics from the source become range-dependent because the water depth changes with source position along the transmission path. To model this dependence, two source locations were used as shown in Fig. 6.

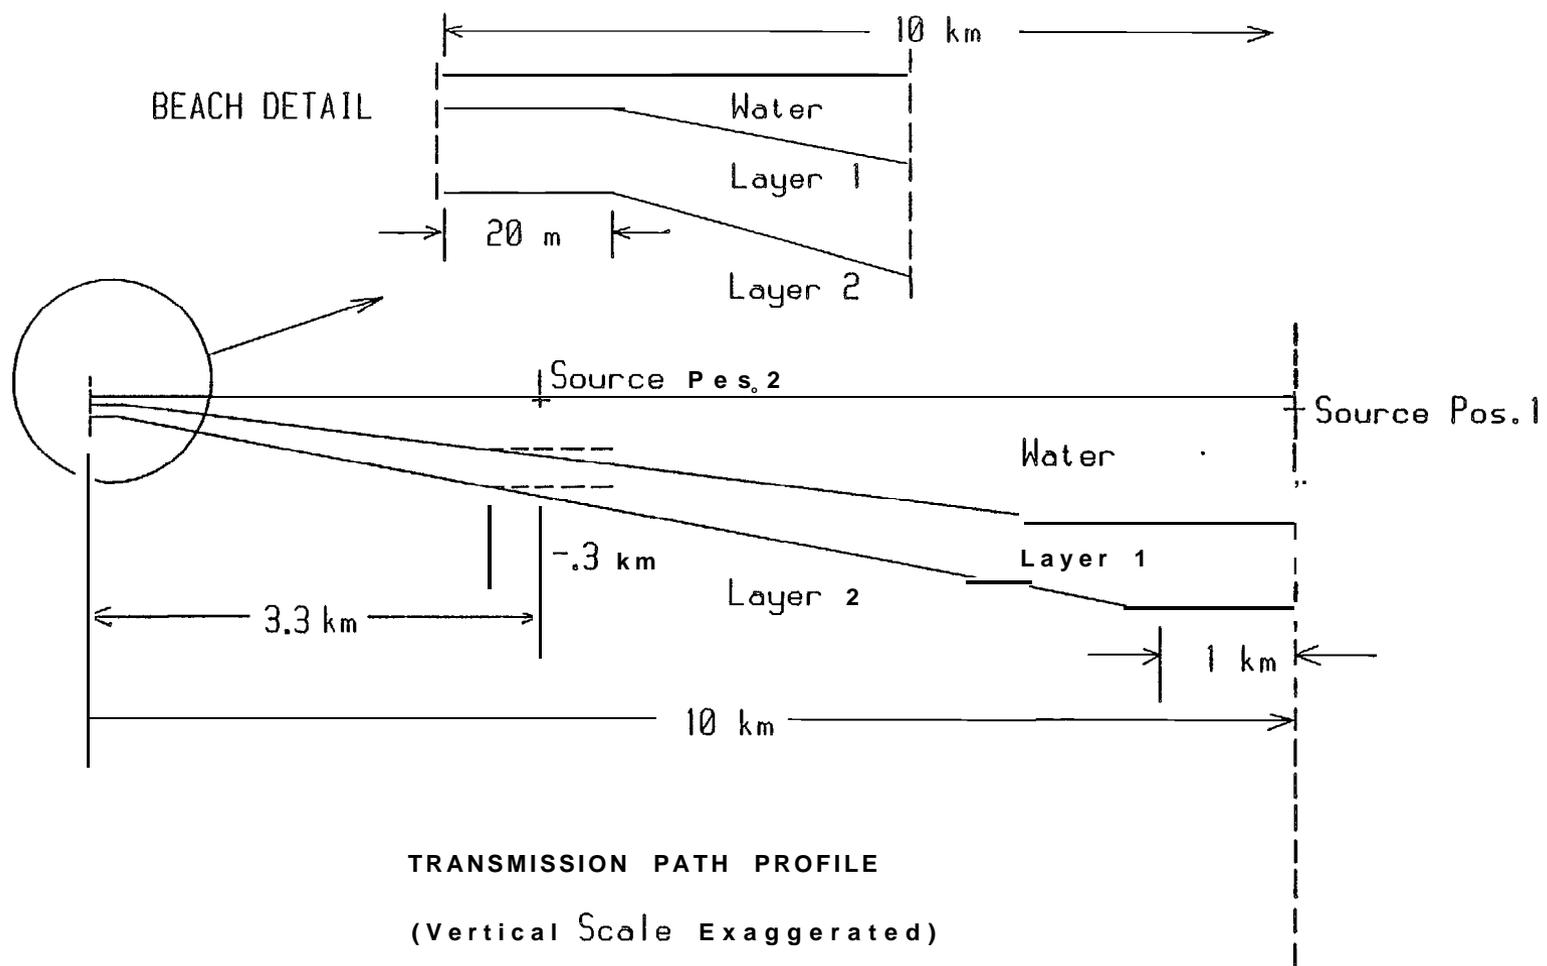

Figure 6. Beach geometry for IFD Model calculation of underwater sound transmission from an offshore source to a receiver near the shoreline.

Table 2 lists the parameter values used in modeling the sound transmission for three different bottom types. Bottom Type 1 represents conditions at Port Moller, Cape Seniavin and Cape Peirce and features a relatively thick layer of fine sand over a deep layer of coarser sand and gravel. Information for this model is based on data obtained from a NOAA survey made by Ertec Western Inc. (1983) and sand properties data reported by Stoll and Bryan (1970). While the Cape Peirce site matches the two other sites with a similar slope of -0.004 , it may have a harder bottom because of rock outcrops. As a result, the TL predictions of the model for the Type 2 rocky bottom may be more appropriate for this site.

Bottom Type 2 represents conditions at the four Pribilof Island sites and features a thin layer of silty, very fine sand over a basalt rock sub-bottom. The model is based on data reported for Bering Sea regions by MacKensie (1973). A bottom slope of -0.01 was used. To determine the influence of the thin sediment layer on sound propagation, a variation of Bottom Type 2 was also used in the model study. This was called Bottom Type 3 and differed from Type 2 by having a very thin, light sand layer over the underlying basalt.

The special case of the site near Ugamak Island was considered by using model results which had been obtained previously for another MMS-sponsored project. These results were obtained for a study of sound propagation conditions near Unimak Island for a uniform water depth of 70 m. The results for this previous study are considered to be relevant since, at a distance of 200 m off the beach, the bottom slope levels off at a depth of 70 m.

The sound speed profile used for all of the modelling work in this study was representative of Bering Sea conditions in spring before the warm summer surface layer has developed. The profile used was nearly neutral with a slight upward refraction effect.

The results of the IFD Model study using the Type 1 Bottom parameters are shown in Figures 7A through 7D. Figure 7D presents the TL characteristics for the two source positions plotted to show TL versus distance from the beach. This is presented as a more relevant format than the usual TL plot showing TL versus range from the source position. The model provides for transmission of

only one frequency for each set of calculations. As a result, the calculated values shown in Fig. 7A for 100 Hz incorporate considerable fluctuations in level caused by multipath interference patterns. The results have been smoothed somewhat by averaging the model-calculated TL over a depth range from 1 to 3 m to derive the solid curves shown in the figure. The dashed lines are the estimated rms-averaged TL characteristics which would be obtained by averaging several model calculations using closely-spaced tones to smooth out the interference pattern.

Figure 7A shows that for a source located 10 km from the beach, the TL becomes greater than 100 dB at range of 6 km from the source or 4 km from the beach. This is essentially the acoustic cutoff for sound at this frequency. For a source located 3.3 km from the beach the cutoff is reached within a few hundred meters of the beach. Note the TL at very short ranges from the source position is about 60 dB. This high value at short ranges is the result of the shallow source (1 m) and shallow receiver depths (2 m) selected for use in the study. This geometry was selected to represent the operating depth of the propellers of small and medium-sized vessels and the swimming depth of pinnipeds near the haul-out sites.

Figure 7B presents the TL characteristics of the Type 1 bottom for 315 Hz. At this frequency the bottom losses are not as severe and transmission from a source at 10 km is not cut off until it gets very near the beach. For a source range of 3.3 km, transmission up to the beach region can be seen to occur. While attenuation rates near the source can be seen to be high as a result of the shallow geometry, a TL plateau is reached wherein a constant level is maintained or the level decreases slowly with increasing distance from the source. This is probably the result of sound transmission within the bottom layers and reflection and refraction out of the layers to reinforce sound in the water column. The TL characteristics shown in Fig 7C for 1 kHz are similar to those obtained at 315 Hz with somewhat lower values of loss being observed.

The TL characteristics obtained from the model calculations for the Type 1 Bottom were interpolated to obtain a set of curves for predicting the TL from a shallow source to a shallow receiver near the beach as a function of

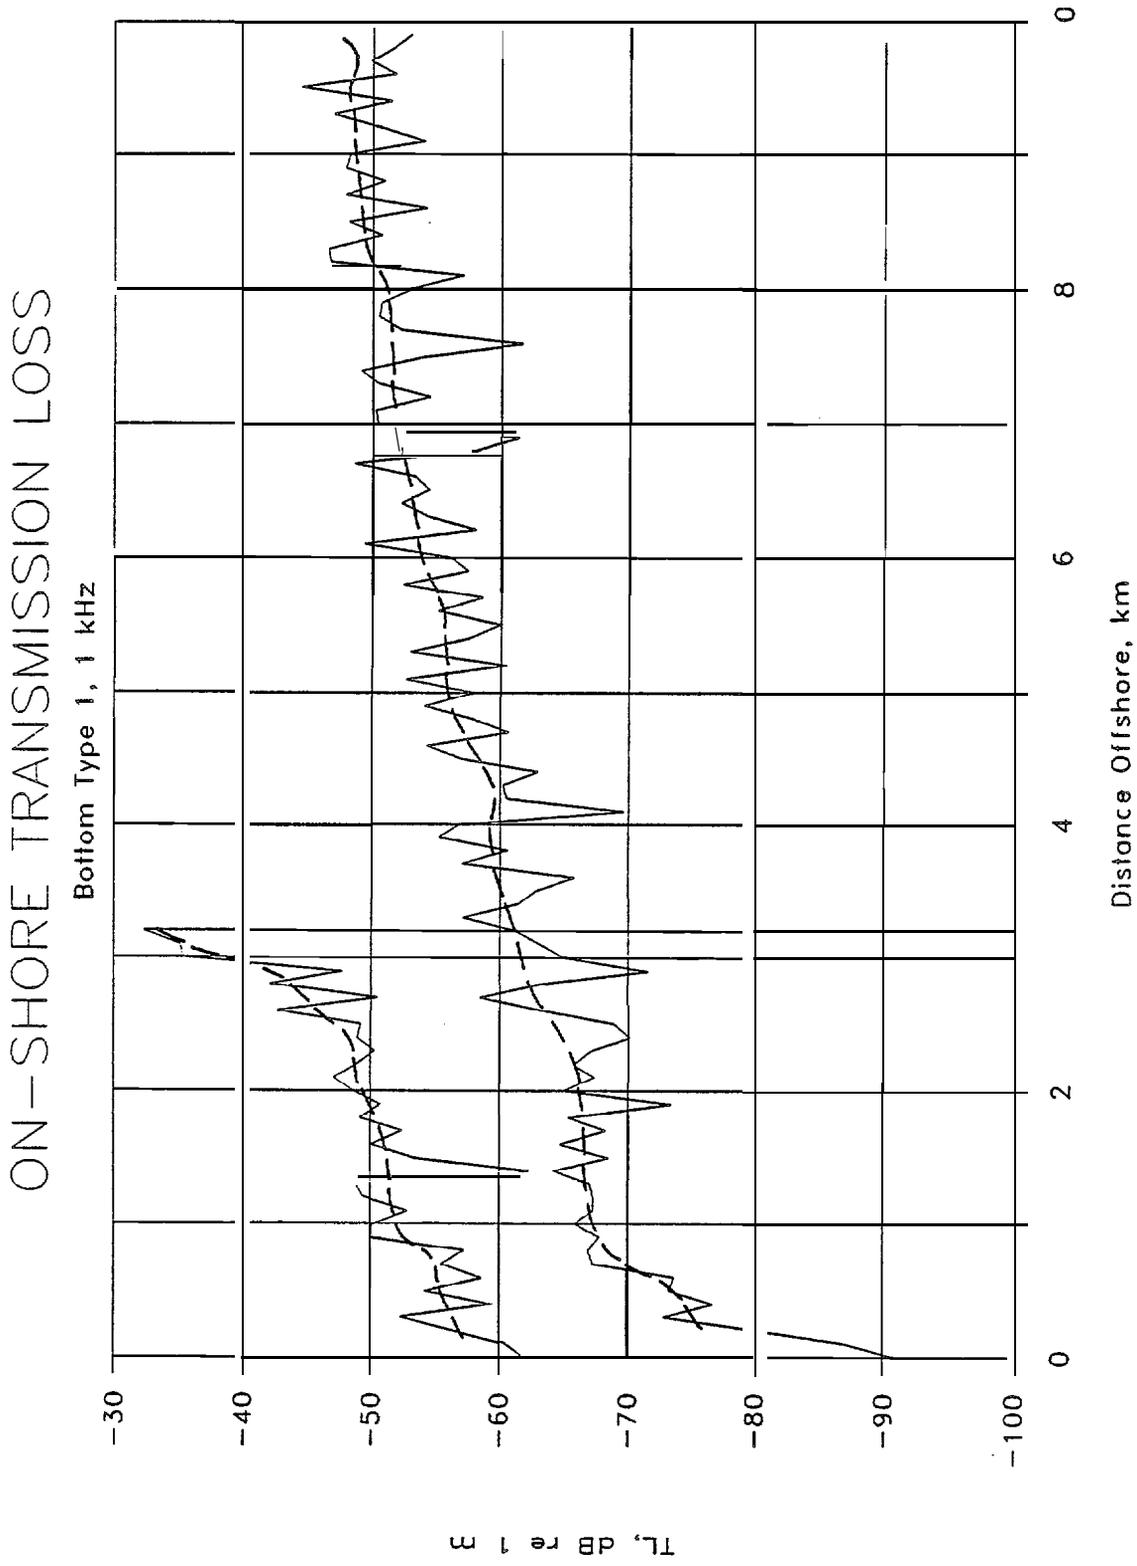

Figure 7C.

the distance of the source from the shoreline. The results, shown in Fig. 7D, are presented to facilitate the estimation of received level near shore for a vessel operating directly offshore. The received level may be estimated as:

$$L_r = L_s - TL \text{ dB re } 1 \text{ } \mu\text{Pa} \quad (3)$$

where: **L_r** = Received level in a selected 1/3 octave band

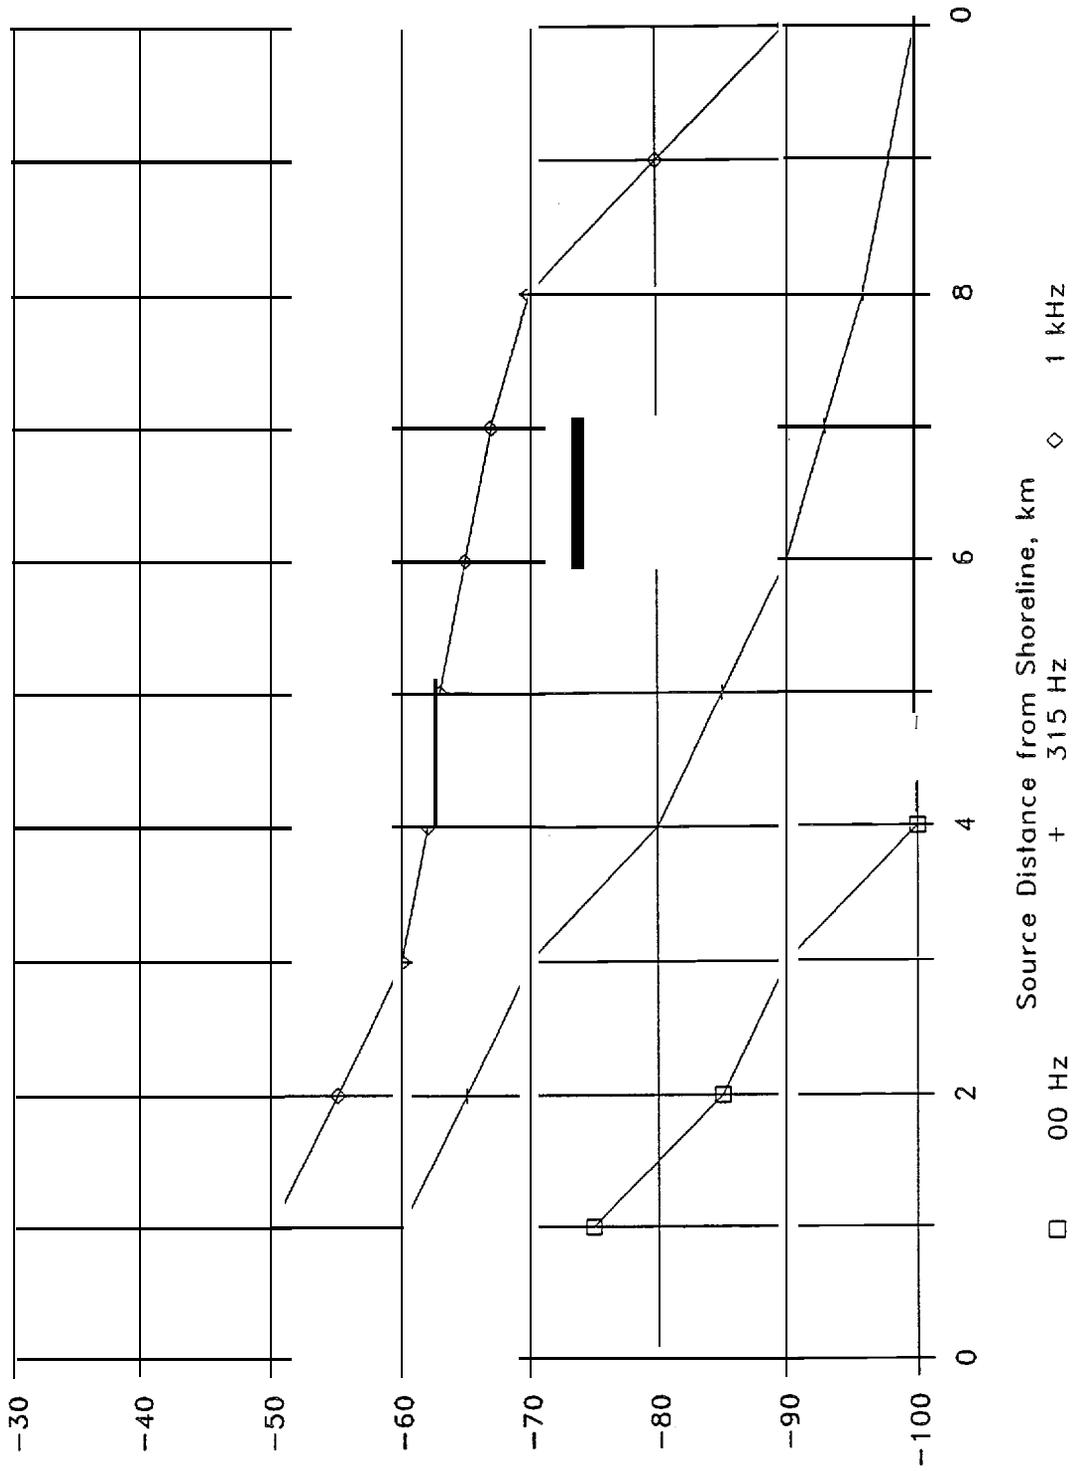

L_s = Source level at 1 m in the selected 1/3 octave band for a specific source (from source level tables)

TL = The transmission loss from Fig. 7D for the 1/3 octave band at the range of interest (this may have to be interpolated)

The transmission loss characteristics calculated using the model with the Bottom Type 2 parameters are shown in Figs. 8A through 8c. Very few differences were found when comparing these characteristics with those for Bottom Type 3 shown in Figs. 9A through 9D. The difference between these two bottom types is a thinner sand layer with less internal damping for Bottom Type 3. The influence of the change in this layer is evident only in some minor details of the transmission characteristics at 1kHz. Therefore the basalt sub-bottom layer is apparently the controlling acoustic influence in determining the TL characteristics for Bottom Types 2 and 3. As a result, the discussion is focussed on the information shown in Figs. 9A through 9D for the Type 3 bottom.

When the TL characteristics at 100 Hz for the rocky bottom (Fig. 9A) are compared with those for the sandy bottom (Fig 7A), the propagation from the source at 10 km offshore can be seen to fall off more rapidly for the rocky bottom than for the sandy bottom. Normally sound transmission over a rocky bottom would be expected to be better than that over a sandy bottom. However in this case, because of the shallow source and receiver positions, most of the sound energy travels between the source and receiver by downward directed ray paths which incur a large number of bottom reflections in the case of the rocky bottom. For the sandy bottom much more sound energy is able to penetrate the bottom and eventually reflect and refract back out into the water layer to reinforce sound transmission at the longer ranges. The TL characteristics at 315 Hz (Fig. 9B) and at 1 kHz (Fig 9C) are similar to those at 100 Hz in that they all show a cutoff at a range offshore of 5 to 6 km for the 10 km source position. For the 3.3 km source position, the differences in TL

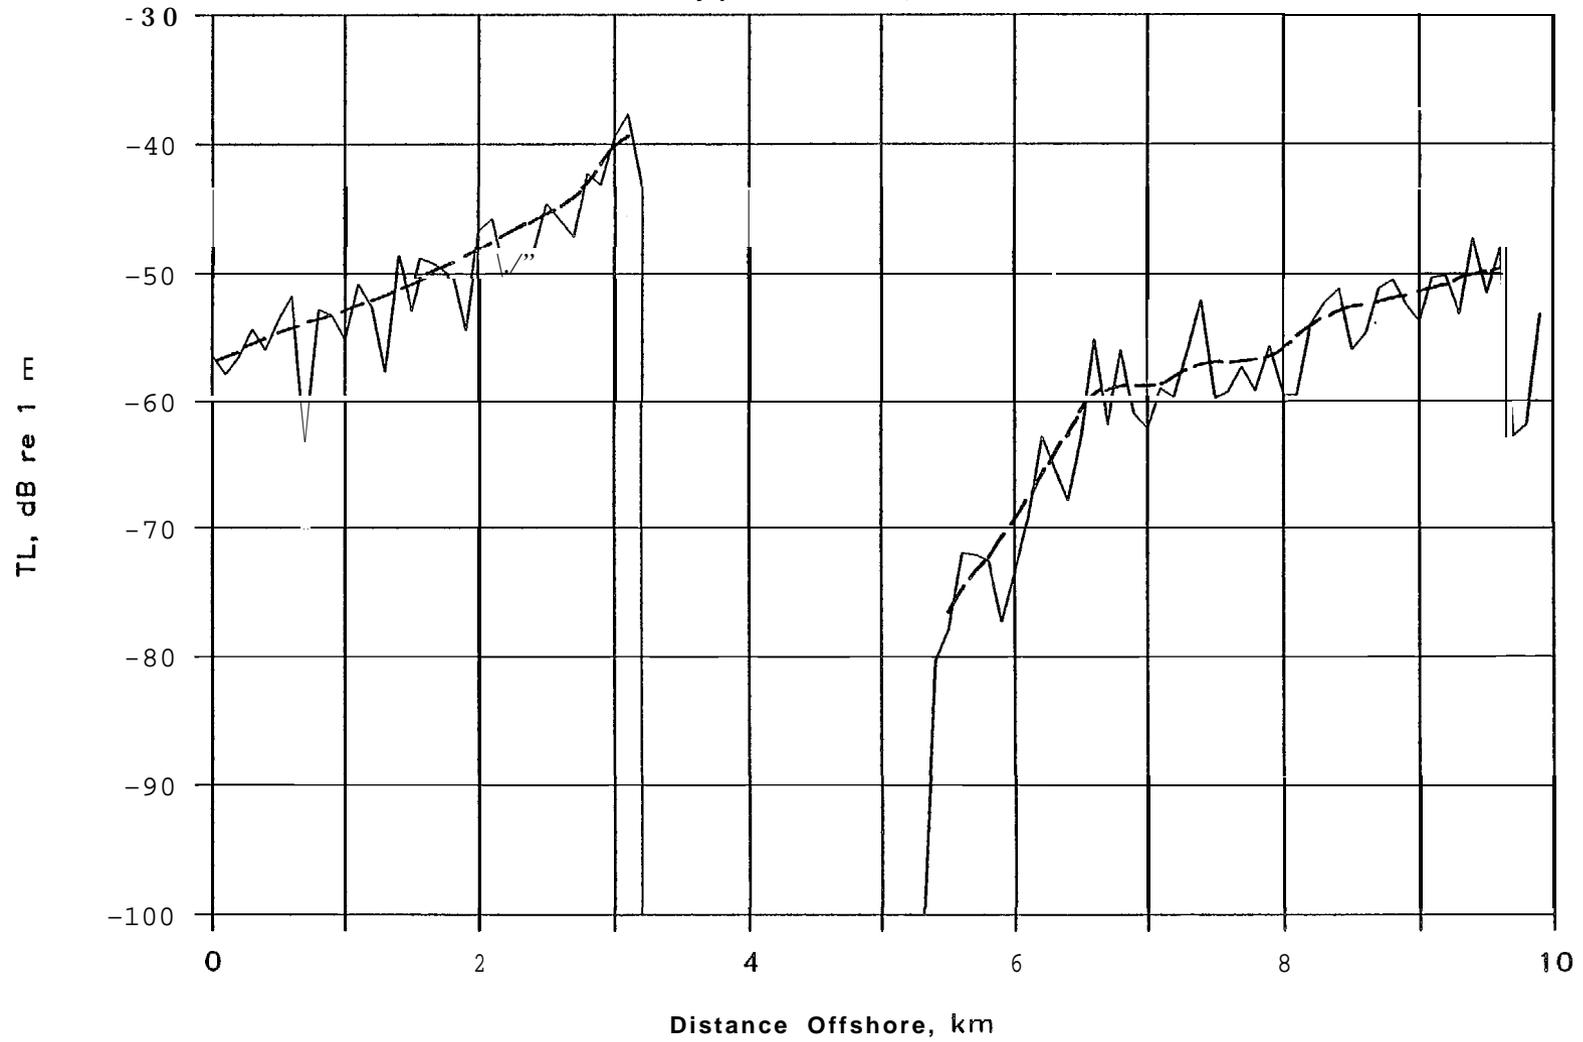

Figure 9C.

characteristics between the Type 1 bottom and the Type 3 bottom are small. The TL near the beach is somewhat less for the rocky bottom than for the sandy bottom.

Figure 9D was developed by interpolation of the model results to obtain curves of TL versus source distance **directly** offshore for the Type 3 bottom. **Comparison** of the results for a rocky bottom (Fig. 9D) with those for a sandy bottom (Fig. 7D) shows that, **while** the TL **is high** at 100 Hz for both types of bottom, **it is** somewhat lower for the rocky bottom. At 315 Hz the TL for the rocky bottom is less than that for the sandy bottom for source distances less than 7 km offshore. For 1 kHz the TL values are similar for source distances less than 4 km, beyond which the TL for the sandy bottom condition is smaller. Thus the model results indicate that for the bottom geometries and parameter values used in the study, a rocky beach has less TL for nearby offshore sources than a sandy beach. While the transmission properties of a sandy beach provide less TL for the more distant offshore sources (>5 km) than a rocky beach, the relatively **high** losses for both types of beaches at these ranges probably makes the difference academic for most of the sources of concern.

The TL characteristics shown in Figs. 10A and 10B were obtained using the IFD Model with a Type 1 Bottom and the layer geometry shown in Table 2 for the 10 km source position. A uniform water depth of 70 m was used. These results were originally obtained to represent conditions near **Unimak** Island and are believed to also be appropriate for conditions offshore from the **haulout** site on **Ugamak** Island, which is directly south of **Unimak**. Figure 10A shows the TL detail for ranges out to 10 km from a source position with Fig. 10B giving the TL characteristics out to a range of 50 km. While the TL characteristics shown in Fig. 10A for 315 Hz and 1 kHz at ranges greater than 5 km appear to be nearly flat, with little additional TL for increase in range, the longer range characteristics of Fig. 10B show that this is part of a broad peak produced by a **multipath** transmission pattern in the TL characteristic. The general trend of the TL characteristics over the entire range out to 50 km follows the general 15 Log (Range) slope expected for shallow water propagation. The characteristic for 100 Hz transmission **is** somewhat lower because of the increased bottom loss at **this** frequency.

Air-To-Water Transmission

Of the several papers available in the literature concerning transmission of sound from air into water, most do not consider the effect of shallow water conditions. **Urick** (1972) presents a discussion of the effect and reports data showing the difference in the underwater signature of an aircraft overflight for deep and shallow conditions. No analysis is presented which **would** permit estimation of the effective TL underwater for shallow water **multipath** transmission conditions. Young (1973) presents an analysis which, while directed at deep water applications, derives an equivalent underwater source for an aircraft overflight which can be used for direct path underwater received level estimates. Unfortunately, for the aircraft - pinniped encounter geometry relevant to this study, the usual source - receiver geometry involves transmission by both direct and bottom reflected paths. Because of this, **it** was necessary to develop an analytical model to help predict the total acoustic exposure level for pinnipeds in shallow water near the path of an aircraft overflight.

The model which was developed provides for calculation of the acoustic energy at an underwater receiver contributed by both the direct sound field and a depth-averaged reverberant sound field. The direct sound field is produced by sound transmitted into the water along a direct refracted path from the airborne source to the underwater receiver. The reverberant sound field is produced by sound reflecting from the bottom and surface as it travels outward from the region directly under the aircraft. An analysis developed by **P.W. Smith, Jr.** based on an earlier study of shallow water sound propagation (Smith 1974) is used to predict the horizontally propagating sound field produced by the reflected sound energy.

Figure 11 shows the geometry and parameters used in **developing** the air-water transmission model. The details of the analysis **are** included in Appendix A with a summary of the general results and an explanation of the use of the model presented in the following discussion. As depicted in the figure, sound from an elevated source **in** air is refracted upon transmission into water because of the difference in sound speeds in the two media. A virtual source location is formed which is the apparent location of the source for the sound

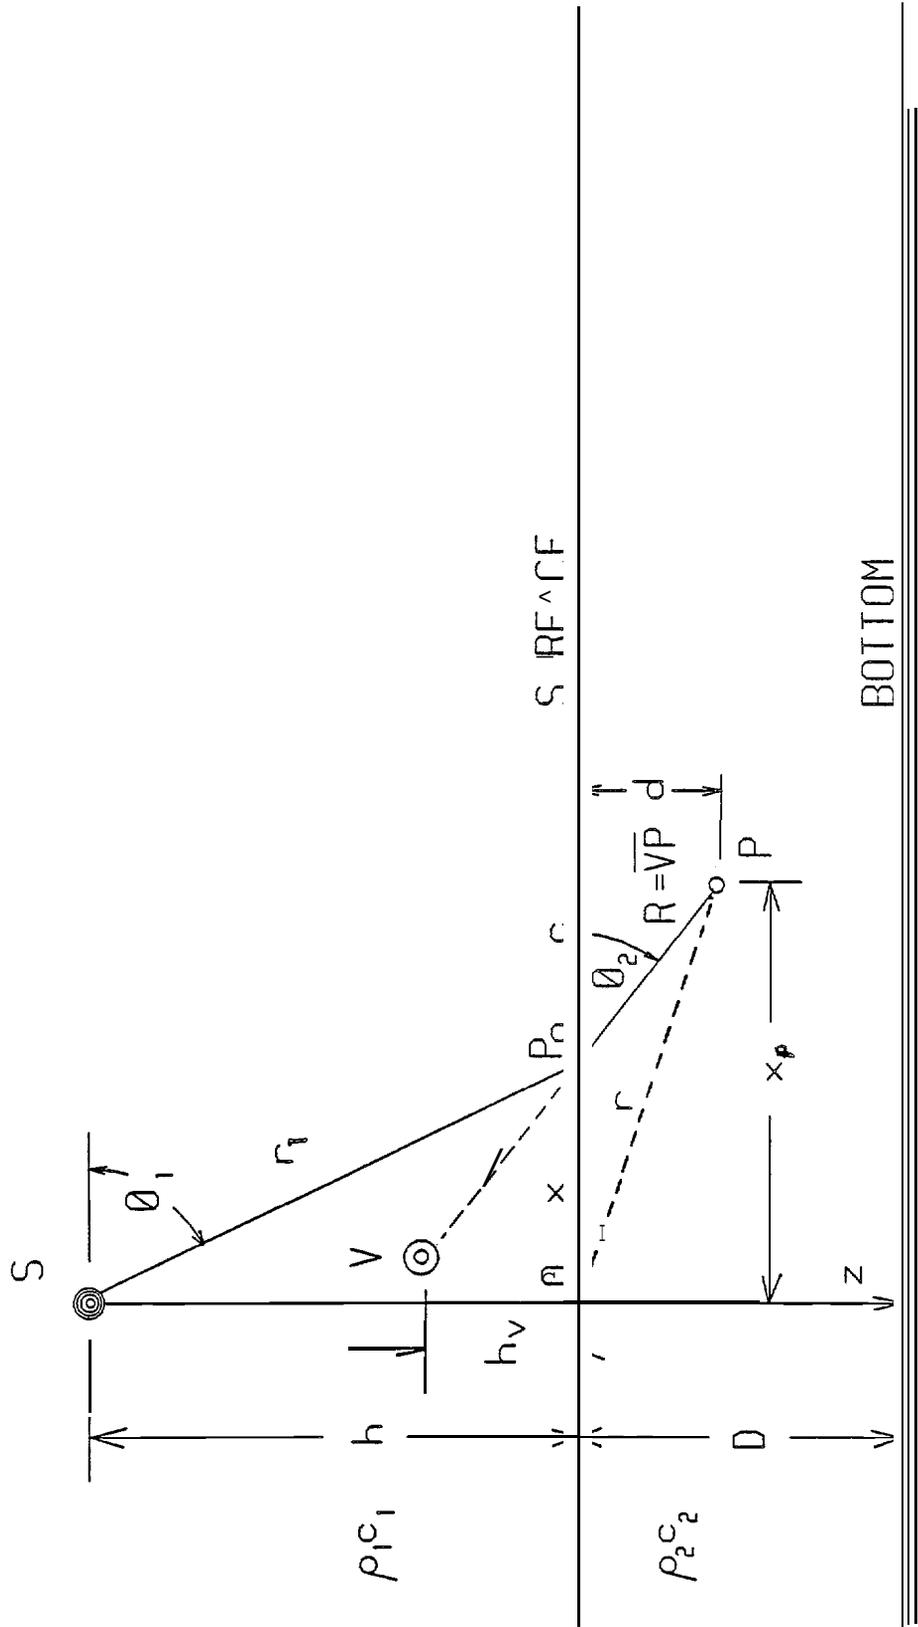

Figure 11. Geometry for air to water sound transmission.

path in water. Because of the large difference in sound speeds between air and water (a ratio of about 0.23) the direct sound path is totally reflected for grazing angles less than 77 degrees. For smaller grazing angles sound reaches an underwater observation point only by scattering from wave crests on the surface, by non-acoustic (**hydrostatic**)² pressure transmission from the surface and from bottom reflections in shallow water. As a result, most of the acoustic energy transmitted into the water from a source in air arrives through a cone with a 26 degree apex angle which intersects the surface and traces a "footprint" directly beneath the path of the source.

For underwater observation points in shallow water within this cone the directly transmitted sound energy is generally greater than the energy contribution from bottom reflected paths. At horizontal distances greater than 1 water depth from the boundary of the acoustic intercept cone on the surface, the energy transmitted by reflected paths becomes dominant and is an important feature of air-to-water transmission in shallow water. Thus two terms become necessary in the air-water transmission model to predict underwater received levels for the full range of expected source-receiver geometries. The theoretical analysis used to develop these terms is presented in Appendix A. The results of this analysis are presented in a normalized, logarithmic form.

Let $A = (h_v + d)/D$ where $h_v = nh$ and $n = c_1/c_2$, the normalized effective source altitude.

$x = x/D$, the normalized horizontal range,

L_r = the underwater sound level, dB re 1 μ Pa.

L_{inc} = the sound level in free air at a distance h from the source (excluding boundary effects), re 1 μ Pa.

Then

$$L_r = L_{inc} + 20\text{Log}(h/D) - 7 + 10\text{Log}[T_d(A,X) + kT_a(b,X)] \quad (4)$$

where $T_d(A,X) = [A/(A^2 + X^2)]^2$ (the direct field transmission factor) (5)

$$T_a(b,X) = 1/X \text{ for } \text{Beta} < 5 \quad (6A)$$

$$T_a(b,X) = (\pi/2b^3X^5)^{1/2} \text{ for } \text{Beta} \Rightarrow 5 \text{ (the channel transmission factor)} \quad (6B)$$

$\text{Beta} = bX/2$, a depth-averaged sound field parameter
(See Appendix A) (7)

$k = 1/(A^2/X^2 + 1)$, a weighting factor for T_a .

²This has been called "evanescent wave" transmission by **Urick** and others. It is important for transmission at low frequencies to receiver locations near the surface.

b = bottom loss factor (see Appendix A)

I = Reverberant energy summation factor (see Appendix A)

The relationship shown in (4) suggests that there is a 7 dB drop in level which occurs as sound passes through the water surface, in addition to the spreading loss. This is correct for the radiated pressure component at some distance from the surface, however close to the surface near field effects occur which cause the underwater pressure to become equal to the pressure in air just above the surface (Urlick 1972). This pressure is double that in the free field at the same range from the source because of the high acoustic impedance of water relative to that of air.

To facilitate computation of TL, the field transmission factors T_d and T_a have been calculated for the normal range of values for **A**, **X**, and **b** as shown in Figs. 12A and 12B. The procedure for calculation of TL using Eqn (4) would proceed as follows:

Given the aircraft altitude (h), receiver depth (d), water depth (D), horizontal distance between the aircraft CPA and the receiver (x_p), and the bottom loss factor (b);

Calculate the normalized height (A), normalized horizontal distance (X), the weighting factor k , and the parameter β ;

Enter Fig. 12A with values of A and X to determine the direct field component, T_d ;

If $k < 0.1$ the direct field is dominant, the T_a component can be ignored, and only the last step of this procedure is needed.

If $\beta < 5$ enter Fig. 12B with values of b and X to determine the depth-averaged field component, T_a ; If $\beta \geq 5$, calculate T_a using Eqn (6B);

Then enter Eqn (4) with T_d , T_a , A , and X and calculate either the transmission loss between the incident sound level and the sound level in water or the sound level in water if the incident level is known.

The procedure for estimating the received level underwater using the calculated TL value requires either measured aircraft signature information or published data from standard flyover tests. If standard flyover data, referred to a sound pressure of 20 μPa and a height of 300 m, are used it is necessary to correct these data to 1 μPa (add 26 dB). If the temperature and relative

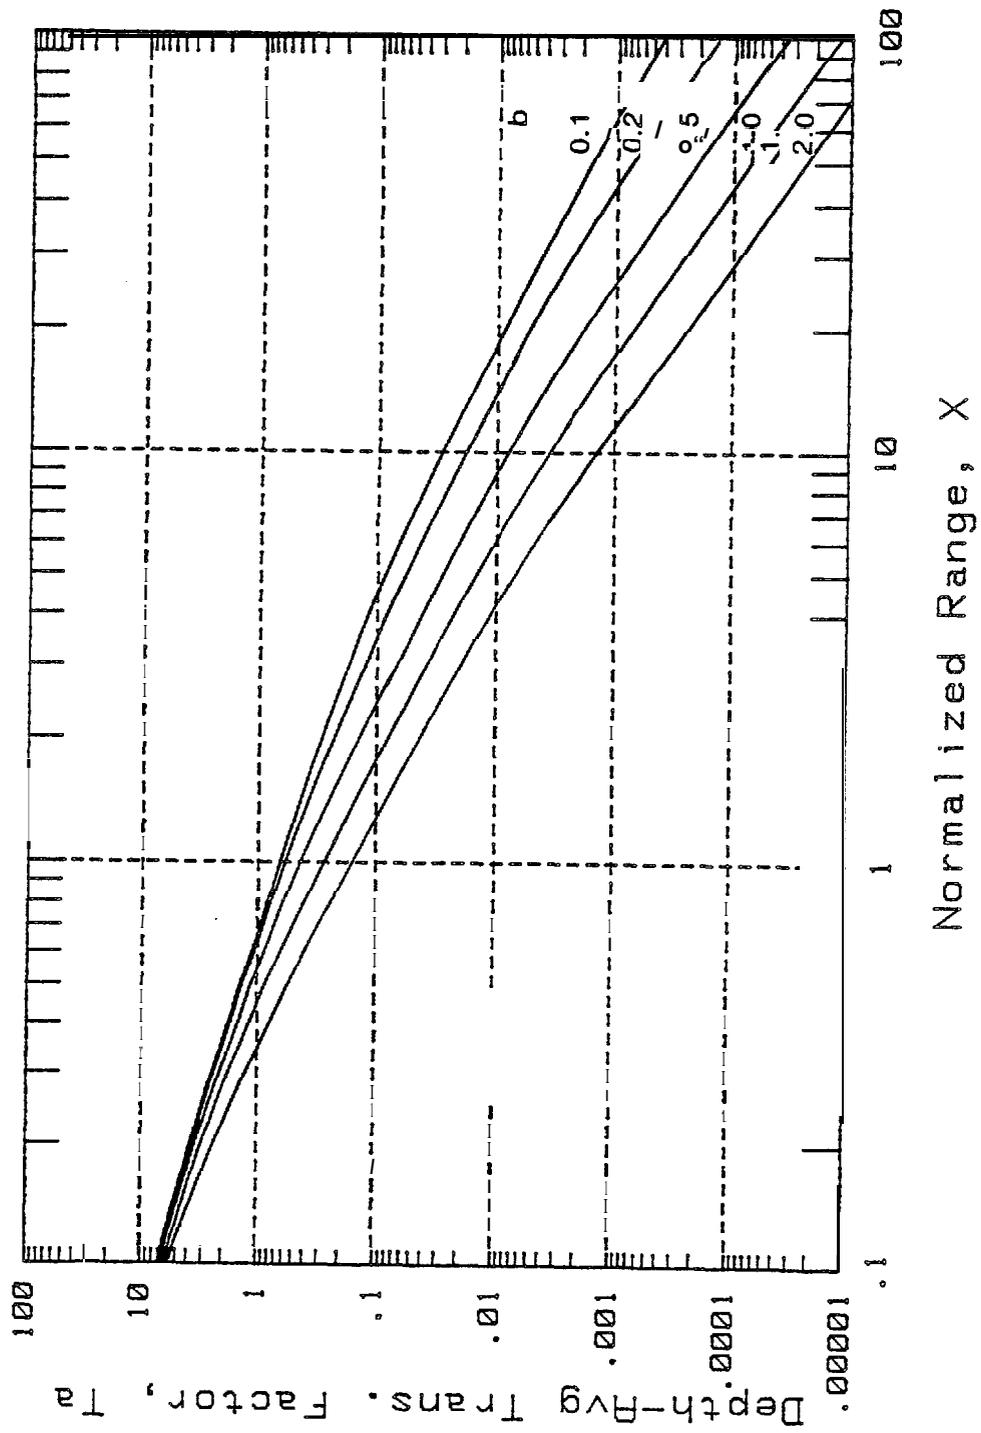

Figure 12B.

humidity for the calculation conditions are greatly different from Standard Day conditions, the corrections given in Table 1 can be applied to the aircraft flyover spectrum to obtain better received level estimates at high frequency. These corrections are applied to obtain the correct sound level value for the high frequency bands at the water surface if the actual flyover altitude is greatly different from the standard test height. The additional absorption loss incurred in the underwater path is generally negligible for the short range transmission considered in this application.

Comparison of Airborne and Underwater Aircraft Noise Spectra

Very few data are available from measurements of aircraft noise in shallow water. Radiated noise spectra obtained from overflights of a Cessna 185 float plane are shown in Fig. 13 (Malme et al. 1982). Of special interest here is the comparison of the airborne and underwater spectra for the overflight at an altitude of 150 m. The water depth at the measurement location was about 40 m. For these measurements the air microphone was mounted on a boat mast about 5 m above the water with the hydrophore located nearby at a depth of 10 m below the surface. The airborne spectra are somewhat higher in level than the underwater spectra at low frequencies, but at high frequencies, the underwater sound levels are significantly higher - possibly as a result of underwater reverberation. The underwater spectrum for a takeoff of this aircraft is also shown for a CPA at a horizontal range of about 100 m with an altitude of about 10 m. The low frequency levels of this spectrum agree well with the takeoff power setting spectrum shown in Fig. 3A for propeller type aircraft. The high frequency spectrum levels for the Cessna 185 underwater data are much higher than those shown in Fig. 3A because of its low altitude, and possibly also as a result of underwater bottom reflection effects.

Underwater radiated noise data reported by Greene (1982) are shown in Fig. 14. These data were measured using a hydrophore depth of 9 m for overflights at an altitude of 150 m of a Twin Otter, an Islander and a Bell 222 helicopter. The data for the two twin engine aircraft may be compared to the reference spectra shown in Fig. 3B. The helicopter data may be compared to the reference data for the Bell 222 presented in Fig. 4A. The results for all

aircraft show good agreement when a 6 dB correction is made for the difference in altitude between the measured data and the reference data.

CONCLUSIONS

The usual location of pinniped rookeries on beaches and rocky shorelines results in this habitat having levels of ambient noise that are closely related to the sea state. Both airborne and underwater ambient noise spectrum levels are expected to be similar because the airborne surf noise is transmitted directly into the water.

The noise sources which may affect pinniped behavior in rookeries are 1-engine and 2-engine aircraft, helicopters, small boats, fishing vessels and cargo vessels. The sound source levels produced by these types of aircraft and vessels have a maximum of about 160 dB at 1 m in a 1/3 octave band. All of these sources present a transient, rise and fall type of noise signature to the rookery area, the rate of which may be an important factor in determining the level of disturbance.

The underwater acoustic transmission properties of the sloping beach found at most rookery sites provide high attenuation of sound arriving from seaward. Rocky sites provide somewhat greater attenuation for distant (>6 km) noise sources than do sandy beaches. Noise sources operating close to shore (<3 km) over a rocky beach are attenuated less than over a sandy beach at the same distance. Frequencies less than 200 Hz are attenuated more rapidly than high frequencies.

The underwater sound levels produced by direct aircraft overflight of shallow water areas are comparable to the levels produced in air near the water surface. There appears to be some enhancement of high frequency sound energy which may be produced by bottom reflection effects. A significant amount of underwater sound energy is transmitted away from the region below the direct path of an aircraft by bottom and surface reflections. Sound transmission characteristics for this propagation have been shown by analysis to follow a 25 Log Range slope which is appropriate for transmission in shallow water from a source located near the surface.

Using several propagation models we determined the characteristics of sound transmission from different potential industrial noise sources in air and water under conditions similar to those at pinniped **haulout** sites. Sound transmission loss curves, i.e., sound attenuation with increasing distance from the source, were computed for situations prevalent at various pinniped **haulout** sites (e.g., various bottom types, water depths, source types and distances from sources; Figs. 7-10). Given the appropriate source sound levels, actual received sound levels at different distances from the source (i.e. at the **haulout** site) may be computed directly from the transmission loss curves. For example, considering sound near 100 Hz, at an offshore location with a specific bottom type, a 160 dB source sound level, which is the maximum expected from most individual sources, attenuates by 90 dB at a distance of 2 km from the source (Fig. 7D).

One may compute actual received sound levels at pinniped **haulout** sites based on our transmission loss curves. By taking into account typical ambient noise levels (p. 91-93), one can also calculate the distance at which a received level drops below ambient and become inaudible. Unfortunately, however, there is no quantitative information describing threshold sound levels which cause disturbance in pinnipeds. This limitation prevents a quantitative determination of the actual zones-of-influence of different sounds produced near **haulout** sites. Attempts to compute zones-of-influence based on qualitative or anecdotal information would be misleading. Carefully designed studies that simultaneously measure sounds (noise) and behavior at active pinniped **haulout** sites are needed to provide the kind of quantitative data necessary to make zone-of-influence computations. Such studies have been conducted or are in progress for some cetaceans, but to our knowledge none have been conducted for pinnipeds.

Thus, without more information, we are unable to take the final step in predicting disturbance responses in pinnipeds from received noise levels at **haulout** sites. It is surprising that this type of information is not available for pinnipeds; however, once it is available, it would be relatively straightforward to apply the information presented in this report to estimate the actual zones-of-influence near pinniped **haulout** sites.

APPENDIX 1-A. TRANSMISSION OF SOUND FROM A SOURCE IN AIR INTO SHALLOW WATER

A.1 Source Strength in Water of an Air Source and Subsequent Response of an Isospeed Channel*

- O: origin
- S: source
- V: virtual source (vertical plane)
- P: observation point
- P₀: surface-breaking point

Snell's law:

$$\frac{\cos\theta_2}{c_2} = \frac{\cos\theta_1}{c_1} \tag{1a}$$

$$\frac{d\theta_1}{d\theta_2} = \frac{c_1 \sin\theta_2}{c_2 \sin\theta_1} \tag{1b}$$

geometrical relations:

$$r_1 = h/\sin\theta_1 \tag{2}$$

$$x = h \cot\theta_1 \tag{3}$$

$$\frac{dx}{d\theta_1} = -\frac{h}{\sin^3\theta_1}, \tag{4}$$

Assuming pressure doubling at surface, continuity of pressure across surface:

$$e_{P_0}: p_2(z=0) = 2p_{inc}(r_1, \theta_1) \quad (\rho_1 c_1 \ll \rho_2 c_2) \tag{5}$$

differential area on surface associated with annulus, $d\theta_1$; using (3) (4):

$$dA = 2\pi x dx = 2\pi h^2 \frac{\cos\theta_1}{\sin^3\theta_1} d\theta_1. \tag{6}$$

*By P.W. Smith, Jr.

differential of power into water, associated with dA :

$$dP = \frac{p_2^2(z=0)}{\rho_2 c_2} \sin\theta_2 dA \quad (7a)$$

$$= \frac{p_2^2(z=0)}{\rho_2 c_2} \sin\theta_2 2\pi h^2 \frac{\cos\theta_1}{\sin^3\theta_1} d\theta \quad (7b)$$

Same dP evaluated as $r/R \rightarrow 1$, $r \sim \infty$:

$$dP = \frac{p_2^2(r, \theta_2)}{\rho_2 c_2} \times 2\pi r^2 \cos\theta_2 d\theta_2 \quad (7c)$$

or, using (1b):

$$dP = \frac{p_2^2(r, \theta_2)}{\rho_2 c_2} \times 2\pi r^2 \cos\theta_2 \frac{c_2 \sin\theta_1}{c_1 \sin\theta_2} d\theta_1 \quad (7d)$$

Equating (7b) and (7c), using (5):

$$r^2 p_2^2(r, \theta_2) = 4h^2 p_{inc}^2(r_1, \theta_1) \frac{\sin\theta_2 \cos\theta_1}{\sin^3\theta_1} \frac{c_1 \sin\theta_2}{c_2 \sin\theta_1 \cos\theta_2}$$

and, using (1a):

$$r^2 p_2^2(r, \theta_2) = 4h^2 p_{inc}^2(r_1, \theta_1) n^2 \frac{\sin^2\theta_2}{\sin^4\theta_1} \quad (8)$$

where $n = c_1/c_2$

Now, using (2) to eliminate h :

$$r^2 p_2^2(r, \theta_2) = 4r_1^2 p_{inc}^2(r_1, \theta_1) n^2 \frac{\sin^2\theta_2}{\sin^4\theta_1}$$

or taking the square root, we get far-field pressure in water:

$$r p_2(r, \theta_2) = 2 r_1 p_{inc}(r_1, \theta_1) n \frac{\sin\theta_2}{\sin\theta_1} \quad (9)$$

Since (air/water) $\sin\theta_1 > 0.97$, it may be neglected.

Range-Averaged Response in Isospeed, Range-Independent Channel

We adapt the analysis of Smith (1974) by (i) making the source strength Ψ (m.s. pressure at a unit range) vary with D/E angle [Smith (1974), Eq. (2)]; (ii) specializing to a range independent medium; (iii) specializing to an isospeed channel.

Making changes (i) and (ii), Eq. (4) of Smith(1974)for the response pressure at horizontal range x becomes

$$p^2(x) = \frac{1}{x} \int_{-\pi/2}^{\pi/2} \frac{2\Psi(\theta)e^{-S(x,\theta)}}{X(\theta) \tan|\theta|} d\theta , \quad (10)$$

where θ = depression angle (radians)

$\Psi(\theta)$ = source strength = $\lim_{r \rightarrow 0} [r^2 p^2(r, \theta)]$, r being slant range from source

$X(\theta)$ = bounce distance

$S(x, \theta)$ = integrated attenuation factor due to boundary reflection loss and volumetric attenuation [Smith (1974), Eq. (7)].

For an isospeed channel, where the rays are straight, we have a bounce distance

$$x(\theta) = 2D/\tan|\theta| \quad (11)$$

where D is the water depth. The value of S, calculated from number of bounces in range x times a loss per bounce in the form

$$dB \text{ loss per bounce} = 4.343 b \sin|\theta| \text{ dB} , \quad (12)$$

is

$$S(\theta) = (bx/2D) \sin|\theta| \tan|\theta| . \quad (13)$$

For a source in air injecting sound into the channel, the directional source strength has been found to be [Eq. (9)]

$$\Psi(\theta) = 4 \Psi_{\text{inc}}(\text{air}) n^2 \sin^2 \theta, \theta > 0; 0, \theta < 0, \quad (14)$$

where Ψ_{inc} is the source strength (m.s. pressure at unit range) of the sound in air incident upon the surface at a depression angle given by Snell's law:

$$\cos \theta_{\text{air}} = n \cos \theta. \quad (15)$$

Hereafter we assume an omnidirectional source in air:

$$\Psi_{\text{inc}}(\text{air}) = \Psi_{\text{air}}, \text{ a Constant}. \quad (16)$$

Finally we note that, for $x \gg 5D$, S is so large at large θ that it is a reasonable approximation to take $\sin \theta \approx \tan \theta \approx 13$ and also to extend the upper limit of integration in (1) to infinity. With these approximations, Eqs. (10) through (16) combine to

$$p^2(x) = \frac{4 \Psi_{\text{air}} n^2}{xD} \int_0^{\infty} \theta^2 e^{-\frac{bx\theta^2}{2D}} d\theta. \quad (17)$$

The integral is found in standard tables. The final result has the form

$$p^2(x) = \frac{\Psi_{\text{air}}}{x^2} n^2 \left(\frac{8\pi D}{b^3 x} \right)^{1/2}. \quad (19)$$

Note that the first factor is the squared-pressure in air at the same range x , assuming spherical spreading. The remaining factors are typically less than unity.

A.2 Combining Direct Path Transmission and Channel Response to Obtain a General Model of Air to Shallow Water Transmission

For underwater receiving points near the source, the **far field** pressure relationship given previously by Eq. (9) must be modified. The exact solution for the sound field in water near a source in air is a complicated relationship which has been discussed by **Urlick (1972), Young (1973) and others**. For **our purposes**, a sufficiently accurate form can be derived by rewriting Eq.(9) as

$$p_d^2(r, \theta_2) = 4n^2 \frac{\psi_{\text{air}}}{r^2} \sin^2 \theta_2 \quad (19)$$

where $\psi_{\text{air}} = r_i^2 p_{\text{inc}}^2$, source strength in air. Let

$$r^2 = (h_v + d)^2 + x_p^2 \quad (20)$$

$$\sin^2 \theta_2 = \frac{(h_v + d)^2}{r^2} \quad (21)$$

Combining (19), (20), and (21), the direct pressure field is

$$p_d^2 = 4n^2 \psi_{\text{air}} \left(\frac{h_v + d}{(h_v + d)^2 + x_p^2} \right)^2 \quad (22)$$

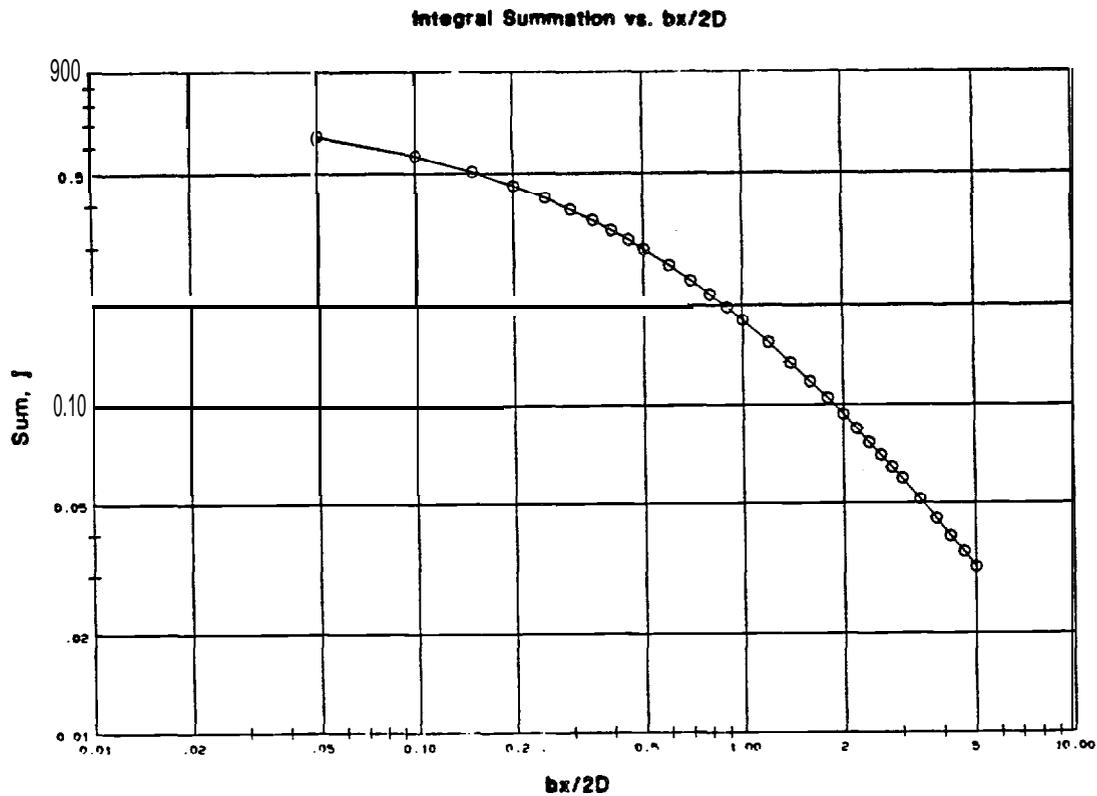

The direct field intensity and the depth-averaged sound channel intensity are combined to obtain a general model for air to shallow water transmission. The depth-averaged transmission given by Eq. (18) was obtained for far-field conditions. To adapt this relationship for conditions closer to the source, it is necessary to solve the integral of Eq. (10) at ranges closer than $x \gtrsim SD$. The exact integral becomes

$$p^2(x) = 4n^2 \frac{\psi_{\text{air}}}{xD} \int_0^{\pi/2} \sin^2 \theta \varepsilon^{-\beta \sin \theta \tan \theta} d\theta \quad (23)$$

where $\beta = \frac{bx}{2D}$ or

$$p^2(x) = 4n^2 \frac{\psi_{\text{air}}}{xD} I(\beta) \quad (24)$$

The integral 1(s) was integrated by computer summation with results as shown below. The integral solution for the depth-averaged path (24) should be used for $\beta \geq 5$. For the region near the source, $x \leq (h_v + d)$, inclusion of the depth-average channel response is not appropriate and the contribution from **the direct path should be considered to represent the total acoustic field.**

Using the above considerations, it is possible to obtain the power sum of the shallow water pressure field by combining Eqs. (22) and (24) or (22) and (18). For $\beta < 5$, we have

$$p_w^2 = 4n^2\psi_{\text{air}} \left\{ \left[\frac{h_v + d}{(h_v + d)^2 + x^2} \right]^2 + k \frac{I}{xD} \right\} \quad (25)$$

For $\beta \geq 5$, we have

$$p_w^2 = 4n^2 \psi_{\text{air}} \left\{ \left[\frac{h_v + d}{(h_v + d)^2 + x^2} \right]^2 + k \left(\frac{\pi D}{2b^3 x^5} \right)^{1/2} \right\}, \quad (26)$$

where

$$k = \frac{1}{(h_v + d)^2 / x^2 + 1}, \quad (27)$$

a weighting factor to automatically reduce the depth-averaged channel component in the region where it is not valid.

Equations (25) and (26) were normalized by the water depth, D and converted to logarithmic form to facilitate plotting. The resulting combined air to shallow water transmission model is:

Let $A = (h_v + d)/D$ where $h_v \approx nh$

$$x = x/D$$

$$L_r = L_{\text{inc}} + 20 \log(h/D) - 7 + 10 \log \left[T_d(A, X) + \frac{T_a(b, X)}{(A^2/X^2 + 1)} \right] \text{ dB re } 1 \mu\text{Pa} \quad (28)$$

where $T_d(A, X) = \left[A / (A^2 + X^2) \right]^2$ (the direct field Transmission factor)

$$T_a(b, X) = 1/X \text{ for } \beta < 5$$

$$T_a(b, X) = (\pi / 2b^3 X^5)^{1/2} \text{ for } \beta \geq 5 \text{ (the channel transmission factor)}$$

$$L_r = \text{The underwater sound level re } 1 \mu\text{Pa}$$

$$L_{\text{inc}} = \text{The sound level in free air at a distance } h \text{ from the source (excluding boundary effects), re } 1 \mu\text{Pa.}$$

Plotted values of $T_d(A, X)$ and $T_a(b, X)$ have been presented previously in Fig. 12.

APPENDIX 2. DESCRIPTIONS AND MAPS OF NORTHERN FUR SEAL HAULOUT SITES IN THE EASTERN BERING SEA (taken from Jordon and Clark 1898, Byrd et al. 1980, Kosloff 1985, NMML files).

Table 2.1. Descriptions of northern fur seal haulout sites in the eastern Bering Sea.

Rookery	Physical Characteristics
St. Paul Island	
Vostochni	Situated on a coarse boulder beach with occasional harems on flat ground above. Intermittent sand beaches are not used as rookeries, but as runways by the bachelor bulls to reach the hauling grounds.
Morjovi	This site is almost continuous with the Vostochni rookery. It is situated mostly on a boulder beach and rocky point extending back from the sea, Bachelor runways are on the intermittent sand beaches.
Polovina	This complex includes Polovina , Little Polovina and Polovina Cliffs rookeries. It is situated partly along a boulder beach and partly on the flats above a series of low cliffs; some scattered harems are along a narrow gravel beach. The Little Polovina portion of this rookery is on a rocky slope.
Lukanin	This site is situated on a rocky slope and at the foot of a series of cliffs.
Kitovi	This site is situated on a rocky beach below columnar basaltic cliffs and on slopes of cinder and lava.
Reef	This site is situated on an irregular beach. The central portion of the rookery extends back from the beach (in a wedge shape) for a considerable distance over a gentle slope strewn with large boulders.
Ardiguen	This site is situated on a rocky beach and rock-slide; the rookery extends to the flat area above and along a narrow beach at the foot of cliffs.
Gorbatch	This site is situated on a boulder beach and at the foot of a slope that extends along a narrow beach at the base of cliffs.

Continued. . .

Table 2.1. Concluded.

Rookery	Physical Characteristics
Tolstoi	Tolstoi rookery is situated on a narrow beach at the foot of cliffs that merge with a long slope strewn with angular boulders; it extends onto a broad, flat sandy beach . This is the most diverse of the St. Paul Island rookeries.
Zapadni	Zapadni rookery is situated on a boulder beach and on a gently sloping upland.
Little Zapadni	This site is situated on an extremely rugged and broken boulder beach and slope.
Zapadni Reef	This site is situated on a narrow, rocky reef and on a beach of boulders.
Sivutch	Sivutch (also known as Sea Lion Rock) is situated on a small crescent shaped islet less than 1 km S of the southern tip of St. Paul Island. It has an abrupt cliff on its southern side that gradually slopes to the north , toward the water . The rookery is on a rocky slope on the north side of the island.
St. George Island	
Staraya-Artil	This site is situated along a narrow belt against steep cliffs. The rookery extends up-slope as far as the seals can climb .
North	This site is situated primarily on a narrow beach at the foot of perpendicular cliffs; some seals move up-slope onto the intermittent rock-slides.
East	This area includes East Reef and East Cliff rookeries. To the west (East Reef) the rookery is situated on a rocky beach, and to the east (East Cliffs) it extends up a rocky slope.
Zapadni	This area includes both Zapadni and South rookeries. They are both situated on a rocky beach that extends up-slope on a long hill .
Bogoslof Island	The rookery at this "site is situated on a gravel-boulder beach immediately south of Kenyon Dome (about 10 m high) on the NW side of the island.

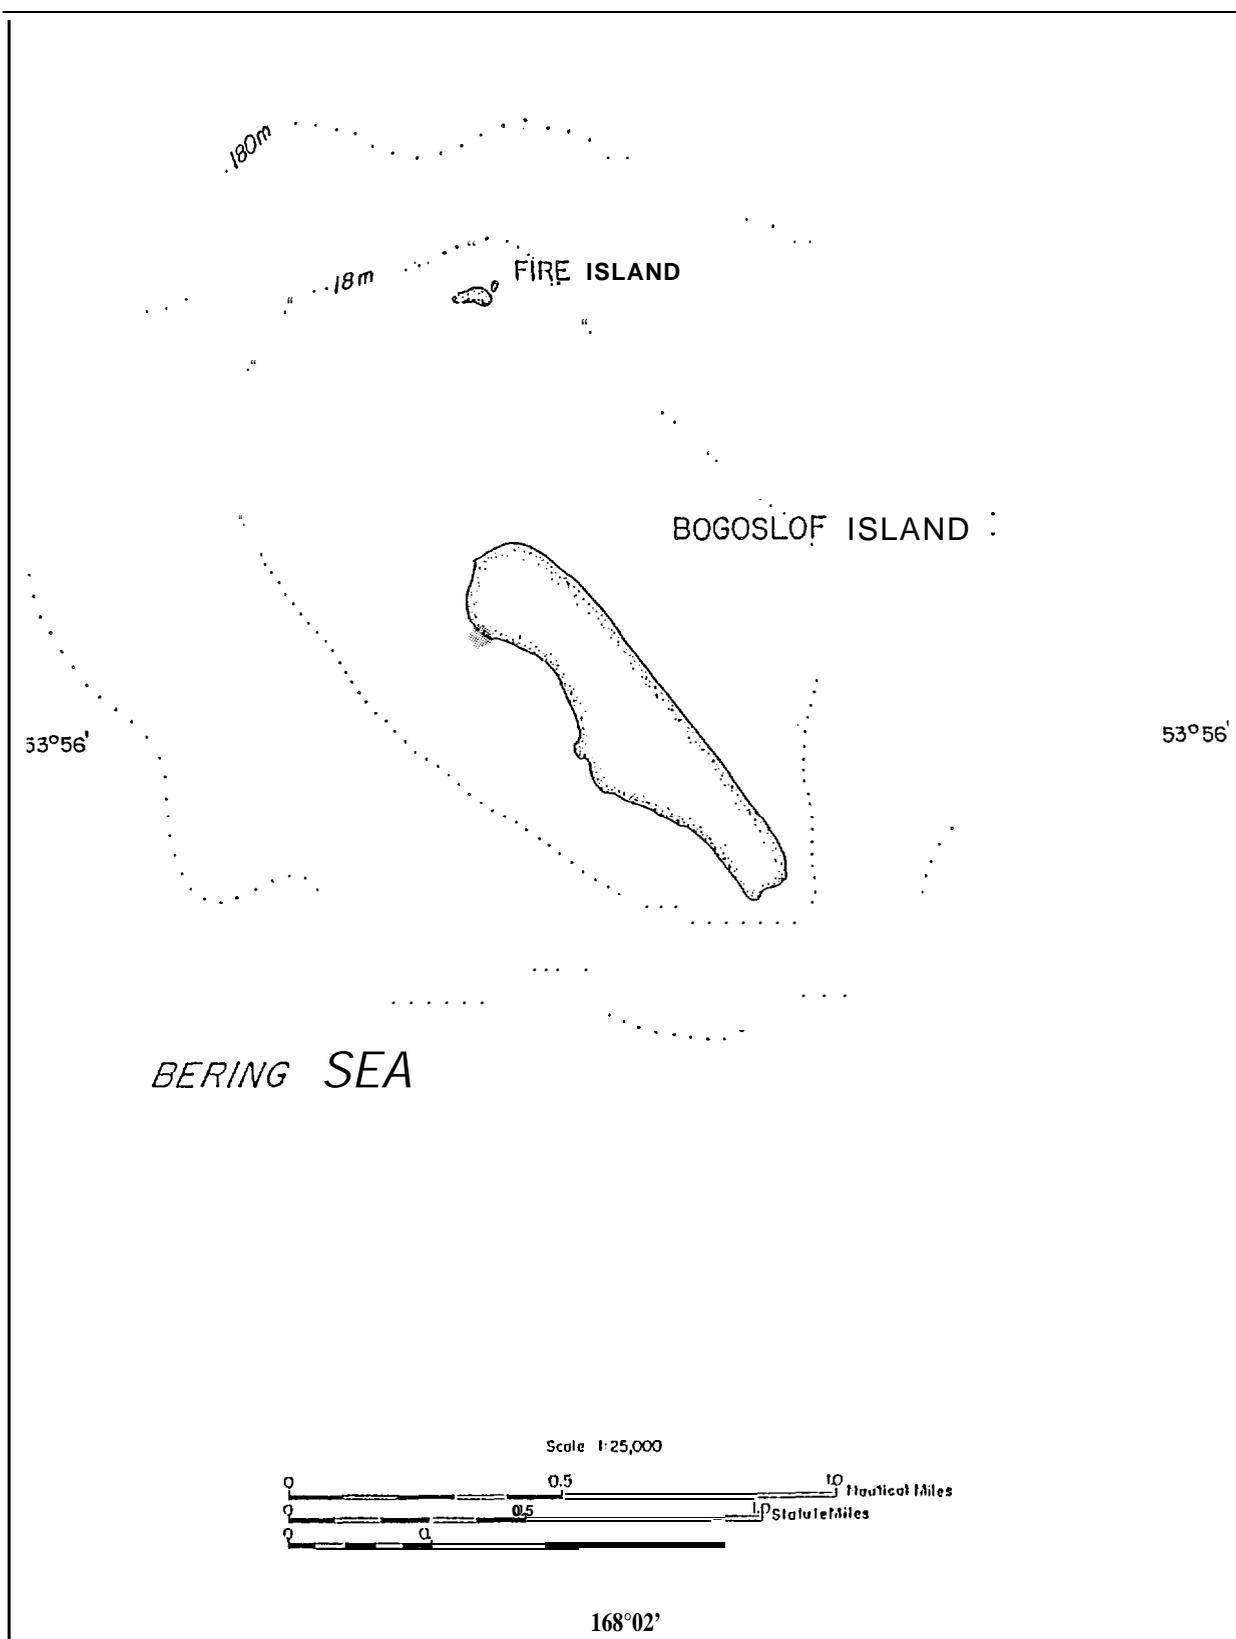

Figure 15. Maps of northern fur seal haulout sites on Bogoslof Island, and on St. George and St. Paul islands and Sivutch in the Pribilof Islands. Scale is 1:250,000 for the index map of the Pribilofs; larger scale maps of Pribilof sites are about 1:34,000. (Maps of the Pribilof Islands are courtesy of the National Marine Mammal Lab., National Marine Fisheries Service, Seattle, WA.)

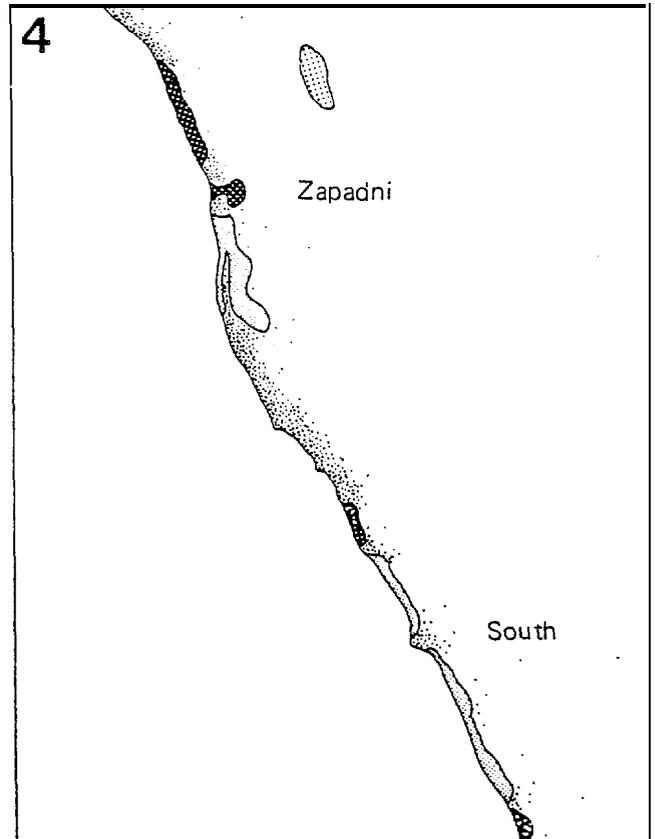

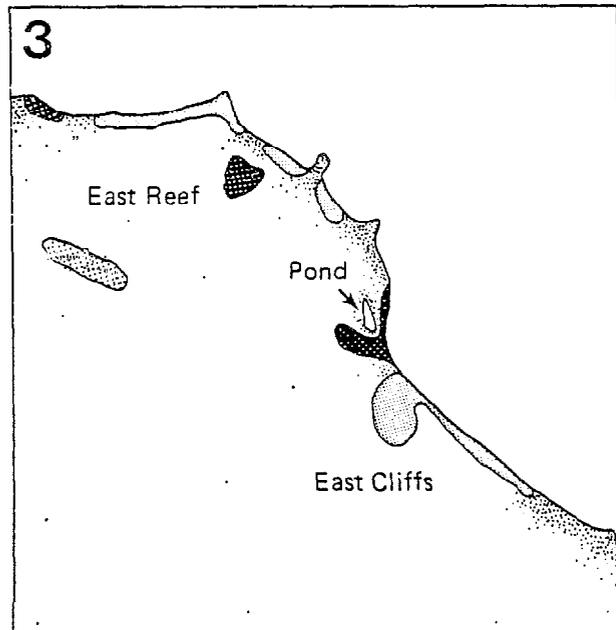

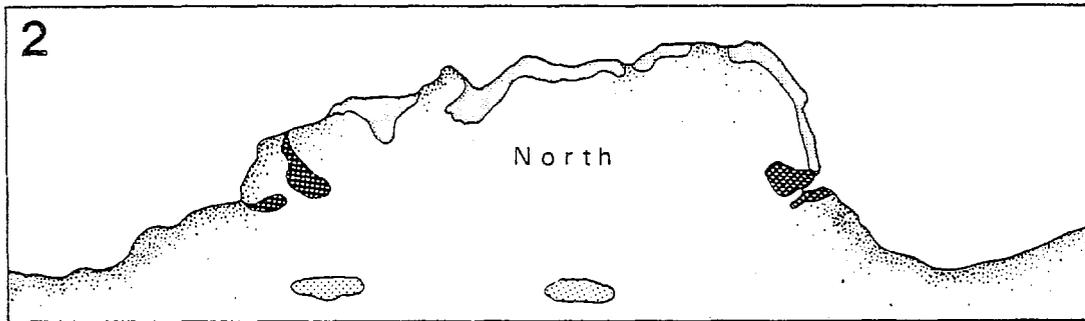

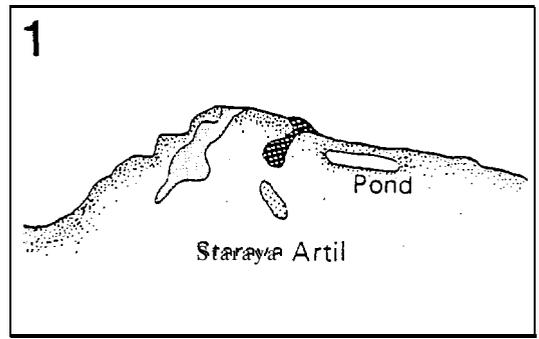

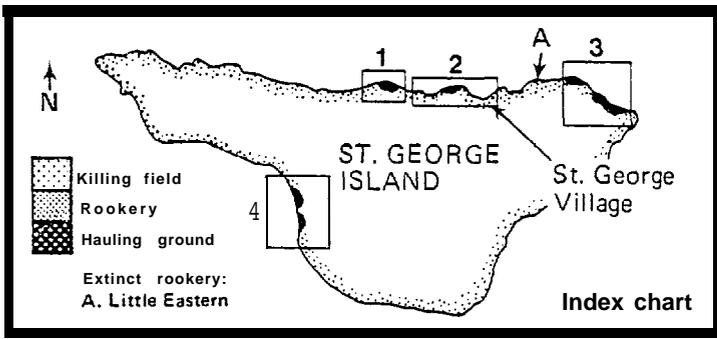

Figure 15. Cone'd.

APPENDIX 3. DESCRIPTIONS AND MAPS OF NORTHERN SEA LION HAULOUT SITES IN THE EASTERN BERING SEA (Sources are many; see APPENDIX 6 for details).

Table 3.1. Descriptions of northern sea lion haulout sites in the eastern Bering-Sea.

Rookery	Physical Characteristics
Bogoslof Island	This hauloutsite is a rookery situated on sand/gravel beaches on the NW end of the island near Kenyon Dome; extensive gravel beaches on the SE side of the island and nearby Fire Island (about 1 km NW of Bogoslof I.) also may be used. Vertical relief is no greater than 12 m at Kenyon Dome or at Castle Rock. Waters are very deep near Bogoslof I. The 18 m isobath is about 500 m from the hauloutsite, the 180 m isobath is about 1 km from the site, and the 1800 m isobath is only about 10 km NE of the site.
Unalaska Island	
Spray Cape	This site is on a point of land along the W side of Unalaska I., just W of Skan Bay. Vertical relief behind the haulout site rises steeply to over 300 m. The 18 m isobath is about 400 m offshore from the site.
Cape Starichkof	This site is located about 10 km NE of Spray Cape. Haulout sites are on rocks and ledges with steep cliffs rising to over 500 m immediately to the SE of the site. The 18 m isobath is within 400 m of shore; the 90 m isobath is about 1-2 km from shore.
Bishop Point/ Cape Tebenkof	These two haulout sites are located several km apart along the N side of the island. Sea lions haul out on rocks and ledges backed by 70 m cliffs at Bishop Pt. and 200 m cliffs at Pt. Tebenkof. The 18 m isobath is within 400 m of shore and the 90 and 180 m isobaths are within about 1.5 and 5 km from shore, respectively
Akutan Island	
Cape Morgan	This haulout site is a rookery situated on a point at the SW end of the island. The W side of the point is composed of a 10 m wide cobble beach backed by 200-300 m high cliffs. The east side of the point

Continued.. .

Table 3.1. Continued.

Rookery	Physical Characteristics
Reef Bight/ Lava Bight	(separated from the W side by Triple Rock) is composed of rocky ledges and islets backed by 200-300 m high cliffs. The 18 m isobath is within 1 km from shore; most of the area near the site is shallower than 100 m deep.
North Head	This complex of sites is located about 10-15 km NW of Cape Morgan in an area of recent lava flow; there are no beaches. Sea lions haul out on rocky basalt ledges that are backed by 20-30 m high bluffs. The 18 m isobath is within 400-800 m from shore; the 90 m isobath is about 8 km offshore.
Akun Island	This site is situated on the north side of Akutan Island about 12-15 km NE of the site at Lava Bight. Sea lions haul out on the islets, rocky ledges, and boulder beaches at this exposed site; it is backed by high bluffs and cliffs. The 18 m isobath is about 1 km from shore and the 90 m isobath is about 5 km from shore.
Billings Head	This haulout site is a rookery; it is situated at the NE end of Akun I. Sea lions haul out mostly at the E end of a 10 m wide and 5 km long cobble/gravel beach, and on boulders and rock ledges backed by 300-350 m high cliffs. The 18 m isobath is within about 200 m from shore; the 100 m isobath is about 1.5-2.0 km to the E . Most of the surrounding area is less than 90 m deep.
Akun Head	The haulout site is situated at the NW end of the island, about 8 km W of Billings Head. Sea lions haul out along a 1 km section of coast on rock ledges and boulders backed by 100-150 m high cliffs. The 18 m isobath is within 100 m from shore; the 90 m isobath is 6-7 km to the N.
Tanginak Island	Tanginak is a small island located about 5 km E of Akun I. Sea lions haul out at N end of the island on boulders and rock ledges backed by 50 m high cliffs. The island is situated within 400 m of the 90 m depth contour.

Continued.. .

Table 3.1. Continued.

Rookery	Physical Characteristics
Tigalda Island	Tigalda I. is about 15 km SE of Tanginak I. Sea lions haul out on rocks, boulders and ledges on the W end of the island (adjacent to Derbin Strait). Vertical relief at the W end is about 30-100 m. The 18 m isobath is within 200 m of shore.
Kaligagan I. and rocks NE of Tigalda I.	Sea lions haul out on rocky ledges primarily on the 2 most northwesterly rocks in this group; vertical relief is no greater than 20 m. The 18 m isobath extends to 200-400 m from most rocks and islets in this group.
Ugamak Island Group	
Ugamak Island	This haulout site is an important rookery; it is currently the largest sea lion rookery in the Alaskan Bering Sea. It is situated on the SE end of the island along a gravel/sand beach about 10 m wide and 10 km long. Vertical relief behind the rookery is about 100 m. The 18 m isobath is within 200 m of shore; most of the area is less than 90 m deep. Sites on rocky beaches and boulder/cobble beaches farther E and N on the island are also used, especially by subadult animals and adults later in the season, after breeding territories at the rookery disintegrate.
Round Island	Considered part of the Ugamak I. rookery. This small island is situated about 1 km S of Ugamak Island . Sea lions haul out on rocks and ledges mostly on the S side of the island. This island is situated in waters 18-30 m deep.
Aiktak Island	This island is about 1 km S of Ugamak Island ; it is about 3.5 km long and 1 km wide, with grassy slopes on N side rising to 100-150 m cliffs on S side . Sea lions haul out on rocks, ledges and beaches, mostly on the N side of island.
Unimak Island	
Cape Sarichef	Sea lions haul out on rocks, boulders, inshore islets and cobble beaches that are backed by 20-30

Continued. . .

Table 3.1. Continued.

Rookery	Physical Characteristics
Oksenof Point/ Cape Mordvinof	<p>m high cliffs and bluffs. The 18 m isobath is about 1.5 km from shore.</p> <p>These two points of land are located about 8-10 km apart along the N side of the island, about half way between Cape Sarichef and Bechevan Bay. Sea lions haul out on rocks, boulders and inshore islets that are backed by 20-50 m high bluffs that rise to a steep headland over 500 m high. The 18 m isobath is about 1.5 km from shore, and the 90 m isobath is more than 20 km to the NW.</p>
Amak Island	<p>Sea lions haul out on the rocks and ledges on the north and east sides of the island. Approximate vertical relief is 10-25 m, rising steeply to 250-300 m. Boulder beaches adjacent to this area also are used occasionally. The 18 m isobath is within 500 m of the island; the 90 m isobath is about 50 km farther offshore to the NW.</p>
Sea Lion Rock	<p>This site is an important rookery. The rock is large--approximately 150 m long, 50 m wide and 15 m high, with sloping access on E, W and S sides. Sea lions mainly haul out on the lower one-third (smooth portion) of the S side of the rock; on some occasions higher levels are occupied. The 18 m isobath is within 500 m of the rock; the 90 m isobath is about 50 km to the NW.</p>
Unnamed Rocks SE of Sea Lion Rock	<p>This haulout site is situated on a cluster of islets and rocks SE of Sea Lion Rock and north of Amak Island. Relief varies from 3-10 m. Bathymetry is similar to Sea Lion Rock.</p>
Right Hand Point	<p>This haulout site is located in northern Bristol Bay. Sea lions haul out on rock ledges and boulder beaches at the point of land, which is backed by steep cliffs rising to 80 m. Waters are shallow in the vicinity of the site; the 5.5 m isobath is 1.5-2.0 km from shore.</p>
Twin Islands	<p>These are the southernmost in the Walrus Islands group, which are located E of Hagemeister Island</p>

Continued. . .

Table 3.1. Continued.

Rookery	Physical Characteristics
	<p>and S of Togiak Bay. Sea lions most consistently haul out on rocky ledges and boulders on South Twin Island. Vertical relief is about 75 m and water depth is over 30 m <2 km offshore from the site. Sea lions also occasionally haul out on the southern ends of nearby Crooked Island and High Island. Both of these sites are also adjacent to steep cliffs (>150 m) and deep water (>30 m).</p>
Round Island	<p>Sea lions haul out on the southern tip of Round Island, which is also one of the islands in the Walrus Islands group. Vertical relief on Round Island is near 500 m, and waters are 30 m deep immediately offshore from the site. Although sea lions also haul out on High Island and on the Crooked Islands, the exact locations are unknown to us and therefore are not indicated on the map.</p>
Hagemeister Island	<p>Sea lions haul out on rocks, boulders and ledges at the south end of the island, near Clam Point. Vertical relief behind the site is over 500 m, and the water is deep (over 30 m) immediately offshore (within 200 m) from the site.</p>
Cape Peirce	<p>Sea lions haul out along 2-4 km of rocky shoreline both N and S of Cape Peirce, and on several rocks about 3 km offshore the entrance to Nanvak Bay. Vertical relief behind most of these sites is from 20-100 m and the 18 m isobath is about 5 km from shore.</p>
Cape Newenham	<p>Sea lions haul out on the rocks, boulders and ledges on the Cape Newenham peninsula, and at the cape itself and on nearby islets. Vertical relief near the site on the south side of the peninsula is about 200 m, and at the cape is about 20 m (low bluffs). The 18 m isobath is about 3-5 km from shore at these sites,</p>
Nunivak Island	<p>Cape Mendenhall</p> <p>A small number of sea lions haul out on the rocks and islets located about 6 km W of Cape Mendenhall. Vertical relief is less than 10-15 m, and the 18 m isobath is located about 3 km to the south.</p>

Continued...

Table 3.1. Continued.

Rookery	Physical Characteristics
Binajoaksmiut Bay	A few sea lions haul out on several small rocky islets (<10 m high) at the mouth of Binajoaksmiut Bay , which is about 25 km NW of Cape Mendenhall , along the S coast of Nunivak Island. The site is about 100 m from shore and water depth within 1 km of the site is less than 10 m; the 18 m isobath is about 8 km offshore to the S.
Nabangoyak Rock	A few sea lions haul out on a rocky islet (<10 m high) about 10 km SE of Cape Mohican, near the W end of Nunivak Island. The 18 m isobath is located about 3.5 km W of the site.
Cape Mohican	This haulout site is located at the extreme west end of Nunivak Island; sea lions haul out on the ledges, rocky islets and boulder beaches. Vertical relief at the cape is about *** m. The 18 m isobath is about 2 km S of this site.
Cape Manning, Cape Corwin , Datheekook Point	Cape Corwin is the SE tip of Nunivak Island; Cape Manning is the NE tip (not shown on maps). However, the exact locations and numbers of animals is unknown, so no maps have been prepared. According to local residents, sea lions also haul out at these sites and at Datheekook Point.
St. George Island	
Dalnoi Pt. Area	This haulout site is composed of rock ledges, boulders and gravel beaches. Vertical relief immediately behind the site is less than 20 m, and nearshore waters at the site are less than 18 m within 2 km from shore.
St. Paul Island	
Northeast Point	This haulout site is situated on a relatively low, rocky, gravel and boulder strewn point of land on the extreme NE end of St. Paul Island. Vertical relief is less than 5 m and water depth adjacent to the site is very shallow; the 40 m isobath is over 10 km from shore and waters 2 km N of the site are less than 2 m deep.

Continued. . .

Table 3.1. Continued.

Rookery	Physical Characteristics
Sivutch	This haulout site (also known as Sea Lion Rock) is situated on a small crescent shaped islet several hundred meters S of the southern tip of St. Paul Island. The islet has an abrupt cliff on its south side that gradually slopes to the north, toward the water. The sea lions haul out on a rocky slope on the north side. Water depth within 500 m off the haulout site on Sivutch is generally less than 5 m.
Otter Island	This small island is located about 8 km SW of St. Paul Island. Vertical relief on the island is over 80 m at its W end , and water depth within 2 km of the site is less than 40 m.
Walrus Island	This small island is an important rookery for northern sea lions . It is <i>located</i> about 12 km E of St. Paul Island; vertical relief behind the site is almost 90 m and water depth within 500 m of shore is generally less than 30 m. The 40 m isobath is located about 1 km E of the site.
St. Matthew Island	
Sugarloaf Mtn.	This haulout site is situated on rocky ledges and boulders at the foot of 300-400 m cliffs and slopes on the southern end of St. Matthew Island. Water depth is less than 18 m along a reef that extends SW of the site as far as Pinnacle I. (about 15 km). Off this reef, water depth increases to 30+ m within a few hundred meters.
Cape Upright	This site is located at the extreme SE end of St. Matthew Island, on rocks, boulders and on ledges at the base of 500 m high cliffs. The 18 m isobath is within 200 m from shore at this haulout site.
Near Lunda Point	Sea lions haul out on a series of low rocks and islets situated 150-200 m offshore from Lunda Point. The 18 m isobath extends about 8-10 km from shore to the NE.
Pinnacle Island/ Gull Islands	This haulout site is located on a series of inshore rocks along the southern shore of

Continued. . .

Table 3.1. Concluded,

Rookery	Physical Characteristics
	<p>Pinnacle Island, which is about 30 km SW of Sugarloaf Mt., and on an island cluster (Gull Rocks) about 0.75 km W of the south end of Pinnacle Island. Vertical relief is great on Pinnacle I. (about 380 m) and the 18 m isobath extends W about 1 km. Vertical relief on Gull Rocks varies from 3-15 m, and the 18 m isobath is within 200 m from shore at this site.</p>
Hall Island	
Arre Rock	<p>This site is composed of several clusters of small rocky islets about 1.5 km offshore from the SW side of Hall Island. Rocks vary in size; vertical relief is from 3-15 m. The 18 m isobath is about 2 km from shore (to the W).</p>
North Cove	<p>The haulout site is located on a medium-sized rock located inshore about 2 km SSE of Cape Hall, at the N end of North Cove; vertical relief about 10-15 m. The 18 m isobath is close (about 1 km) to shore in this area, and the 60 m isobath is within about 5 km from shore.</p>
Elephant Rocks	<p>Sea lions haul out on mainly on a small islet (S. Elephant Rock) in a cluster of inshore islands north of Cape Hall; vertical relief of the rocks is about 3-15 m. The 18 m isobath is less than 1 km from shore from the site; the 60 m isobath is within about 5 km from shore.</p>
St. Lawrence Island	
Southwest Cape	<p>This haulout site is characterized by gravel and boulder beaches backed by low bluffs up to 15-20 m high. Numerous rocky inshore islets up to 5-10 m high are most consistently used by sea <i>lions</i>. Water depth within 400 m of this site is generally less than 18 m.</p>
Punuk Islands	<p>Sea lions haul out on the rocky, boulder beaches along the SE sides of the Punuk Islands, but most regularly only on South Punuk Island. Vertical relief near the haulout site is no greater than 5-10 m, and the 18 m depth contour is about 5 km from shore to the S and extends uninterrupted 20 km N to St. Lawrence Island.</p>

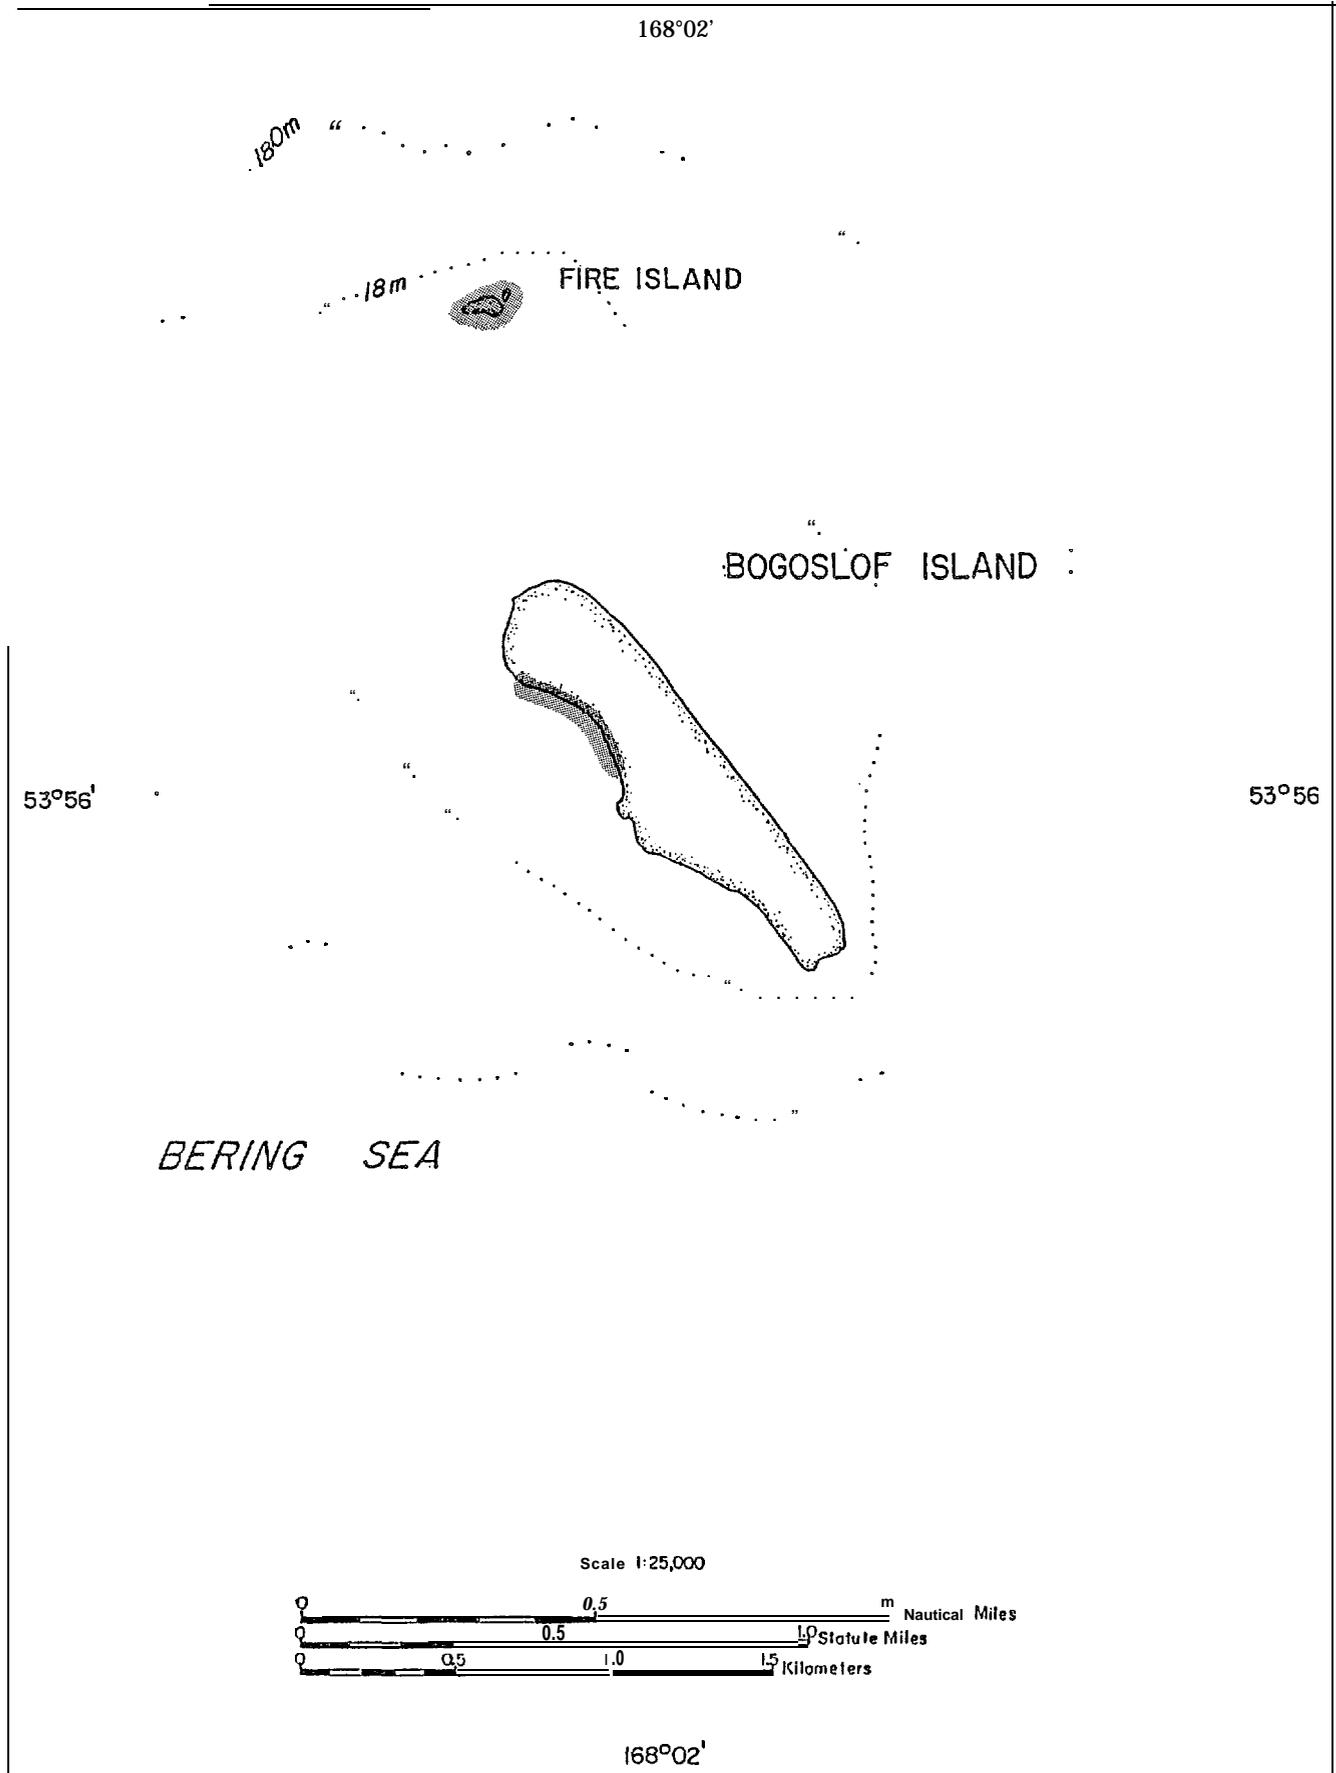

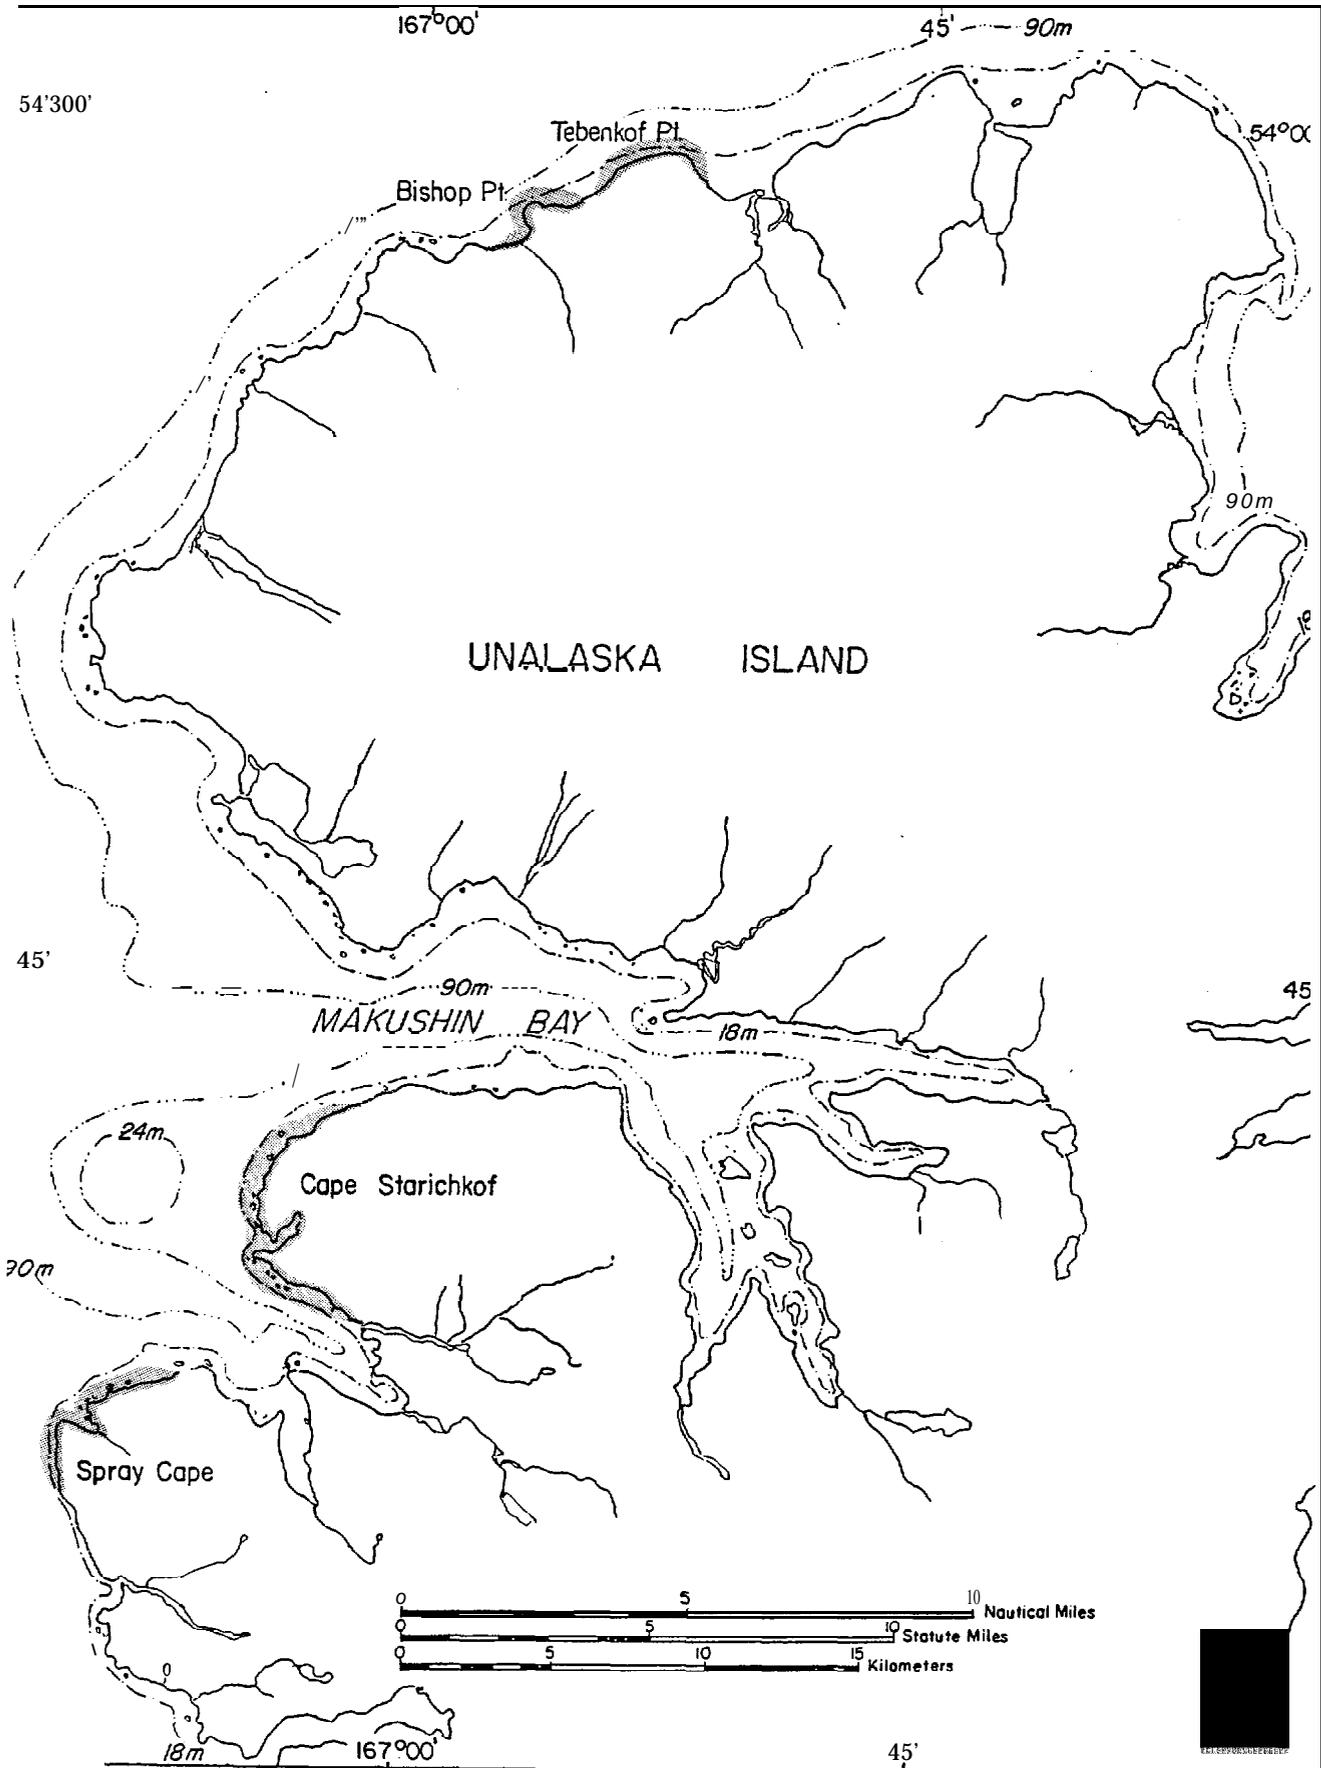

Figure 16. Maps of important northern sea lion haulout sites in the eastern Bering Sea. Bogoslof and Fire islands are shown at a scale of 1:25,000. All other maps are at scales of 1:250,000.

APPENDIX 4. DESCRIPTIONS AND MAPS OF HARBOR SEAL HAULOUT SITES IN THE EASTERN BERING SEA (Sources are many; see APPENDIX 7 for details).

Table 4.1. Descriptions of harbor seal haulout sites in the eastern Bering Sea.

Rookery	Physical Characteristics
Fox Islands	<p>Harbor seals haul out at low to moderate densities at a number of locations in the Fox Islands, especially at low tide when more available haulout habitat is exposed. Small numbers of harbor seals may be seen hauled out at virtually any location in the Fox Islands and on Bogoslof Island, therefore, maps showing specific haulout sites have not been prepared. Recent reports include seals hauled out on rocks and ledges at the E end of Umnak I., on Bogoslof I., Unalaska I., Unalga I. (including The Babies), Akutan I., Akun I. (incl. Tangik I.), Tanginak I., Avatanak I., Tigalda I., Kaligagan I. and other rocks NE of Tigalda I., and on Ugamak and adjacent Round and Aiktak islands. Vertical relief at these sites varies considerably, but generally most sites on the larger islands are backed by bluffs and cliffs rising from 60 to over 500 m in height. Other sites on rocks and smaller islets are considerably lower in relief (1-10 m). Waters are very deep throughout the Fox Islands. The 200 m isobath is only 2-3 km N of Umnak, Unalaska and Akutan islands. Bogoslof I. lies within 10 km of the 2000 m isobath. The only relatively shallow areas (<18 m deep) in the Fox Islands are very nearshore (<1-2 km) on the N side of Umnak I., N of Avatanak I., around the rocks NE of Tigalda I., and S of Ugamak and Aiktak island. Most other areas are in waters much deeper than 60 m.</p>
Unimak Island	
Cape Lapin	<p>Harbor seals haul out on the rocks, ledges and islets (especially at low tide) at the Cape and immediately offshore from there. Vertical relief at the sites varies from 1-30 m, and the 18 m isobath is about 3 km from shore to the N.</p>
North Creek	<p>Seals haul out on rocks and ledges, especially at low tide. Vertical relief immediately behind this site varies from 3-30 m and waters are relatively shallow (<18 m) out to at least 5-7 km offshore.</p>

Continued. . .

Table 4.1. Continued.

Rookery	Physical Characteristics
Cape Krenitzin	Harbor seals haul out on the extensive beaches and sandbars at Cape Krenitzin and nearby islands at the entrance to Bechevin Bay. Vertical relief in this area generally does not exceed 1-5 m and the waters within 6 km are generally less than 10 m; the 18 m isobath is about 7 km offshore (N) from this site.
Isanotski Islands	This site is situated on several very small islands located deep within Bechevin Bay, immediately E of Unimak Island. Vertical relief at the site is generally less than 1 m, depending on the condition of the tide. Water depth also varies with the tide, but is generally less than 1-3 m near the islands, also depending on the proximity to drainage channels.
Izembek Lagoon and Moffett Lagoon	This is an important haulout area for harbor seals in the Alaskan Bering Sea. Haulout sites in Izembek Lagoon (and contiguous Moffett Lagoon) are composed of a variety of mud and sand bars scattered throughout the area. One of the most heavily used areas is in the Moffett Point-Newmann Island area, at the NE entrance to Izembek Lagoon. Vertical relief at this location varies from 1-3 m and water depth varies (1-4 m) with tide conditions.
Amak Island and Sea Lion Rock	Harbor seals haul out primarily on a broad flat area of boulders and rocks on the S and E sides of the island, which are exposed at low tide. Nearby boulder beaches with intermittent gravel and sand also are used. Vertical relief varies from 1-3 m on the S side and up to 20-30 m on the E side. Water depth varies with tide condition (1-10 m). Harbor seals also haulout on nearby Sea Lion Rock, at the periphery of the rookery when northern sea lions are present and more widespread when sea lions are absent.
Cape Leiskof	This site is located about 55 km NE of Moffet Pt. Harbor seals haul out on rocks and ledges and sand and gravel bars exposed at low tide. Vertical relief behind this site is generally less than 5-10 m, and the 18 m isobath is relatively close to shore immediately offshore from this site (about 1-2 km).
Port Moller	This is a major haulout site for harbor seals in the Alaskan Bering Sea. They haul out on sand, mud and gravel bars primarily south and west of the entrance to

Continued. . .

Table 4.1. Continued.

Rookery	Physical Characteristics
	<p>this embayment. Broad expanses of mud and sand flats exposed at low tide around the (1) Kudobin Islands, (2) at the entrance to nearby Nelson Lagoon, and (3) on the exposed tide flats around Deer Island (adjacent to Hagus Channel) are used extensively by harbor seals. Very little vertical relief is present at these sites (1-2 m) except near Deer Island (5-10 M), and water depth varies greatly with tide conditions and proximity to major drainage channels (1-10 m).</p>
Cape Seniavin	<p>This site is composed of rocks and boulders, many of which are exposed at low tide, and are backed by 30 m high cliffs. Narrow gravel and sand beaches on both sides of the Cape, backed by 30 m high cliffs, also are used as haulout sites by harbor seals. The 18 m isobath is located about 7 km from shore at this location.</p>
Seal Islands (Ilnik)	<p>This is a major haulout site for harbor seals in the Alaskan Bering Sea. The site is composed of a long stretch (over 25 km) of low sand and gravel barrier islands, and sand, gravel and mud flats and bars exposed at low tide. There is very little vertical relief in the general area (1-5 m). The 18 m isobath is quite close to shore on the seaward side of the islands (<1.5 km). Water depth varies greatly inshore (about 1-5 m), depending on tide conditions and proximity to drainage channels.</p>
Port Heiden	<p>This is a major haulout site for harbor seals in the Alaskan Bering Sea. They haul out on the sand bars and spits and exposed mud and sand flats from Strogonof Pt. to Chistiakof I. and adjacent areas. Vertical relief is very low in this area--generally less than 1-3 m, and water depth varies from less than 1 m to over 3 m, depending on tide condition and proximity to drainage channels. The 18 m isobath is 5-6 km offshore from the entrance to the Port Heiden estuary.</p>
Cinder River	<p>This had been a major haulout site for harbor seals in the eastern Bering Sea. The most extensively used areas were the tidal flats offshore from the mouth of the river. Vertical relief in the area is generally less than 2 m, and water is shallow (<18 m) out to about 20 km from shore.</p>

Continued. . .

Table 4.1. Continued.

Rookery	Physical Characteristics
Ugashik Bay	This is an important haulout area for harbor seals. The shallow sand and mud bars in the estuary south of South Spit and Smokey Pt., as well as the shallow bars and spits offshore from the estuary that are exposed at low tide are used extensively by harbor seals. Vertical relief in the area is generally less than 1-3 m, and the 18 m isobath is about 20 km offshore.
Egegik Bay	This series of sites is situated on the sand, mud and gravel bars, spits and flats in and immediately offshore from the Egegik River estuary at the mouth of the King Salmon and Egegik rivers. Vertical relief near most sites generally varies from 1-3 m and water depth is generally less than 10 m throughout the area. The 18 m isobath is at least 20 km from shore in this area.
Deadman Sands	This site is located midway along the north coast of Kvichak Bay, in NE Bristol Bay near the mouth of the Kvichak River. Harbor seals haul out on the sand, mud and gravel bars and beaches, especially at low tide when extensive areas are exposed. Vertical relief in the area is generally less than 1-3 m, and water depth varies generally between 1-3 m depending on tidal conditions and proximity to drainage channels.
Cape Constantine	Harbor seals haul out on sand, mud and gravel flats and beaches generally W and N of Cape Constantine. Vertical relief in the area is generally less than 10 m immediately along the coast and much less (<1-2 m) farther from shore, depending on tidal conditions. Waters are generally less than 1-3 m deep for several km away from shore; the 18 m isobath is about 10 km offshore all along this section of coast.
Tvativak Bay	Harbor seals haul out on the sand and mud flats in the bay and on the sand and mud flats SE of the bay along the coastline. Vertical relief near the entrance to the bay varies from 3-15 m with a high point (300 m) about 1 km inland E of the bay; along the coastline SE of the bay, vertical relief is around 3-5 m. The 6 m depth contour is probably no more than 2-3 km from shore and the 18 m contour is 25 km SW of this site.
Black Rock	Harbor seals haul out on the gravel beaches and rocks around the perimeter of this small island. Vertical relief is about 40 m at this site and the 6 m depth

Continued. . .

Table 4.1. Continued.

Rookery	Physical Characteristics
	contour is about 1-2 km from shore. Small numbers of harbor seals (2-38) also haul out on nearby High Island, Round Island, Crooked Island, The Twins and Summit Island. However, the exact locations and numbers at each site are unknown, therefore no maps were prepared for these sites (see p. 167 for locations of these islands).
Hagemeister Island	Harbor seals haul out on the gravel beaches and rocks in the Clam Point area at the south end of the island. Vertical relief behind the site is over 500 m, and the water is deep (over 30 m) immediately offshore (within 200 m) from the site.
Nanvak Bay	This is an important haulout area for harbor seals in the Alaskan Bering Sea, and is one of the northernmost pupping areas for this species in the Bering Sea. They haul out on a series of low sand and mud bars exposed during low tide in the main channel leading from Nanvak Bay . Vertical relief is normally less than 1 m and water depth varies (1-3 m) depending on tide conditions. Early in the season spotted seals also haul out at this site; a small proportion of seals at this site during summer also are spotted seals.
Cape Newenham	Harbor seals haul out on the rocks, ledges and beaches at Cape Newenham and on nearby islets. Vertical relief at the Cape is about 20 m (low bluffs) and water depth is over 30 m about 3 km from shore.
Chagvan Bay	Harbor seals (and spotted seals in spring) haul out on sand, mud and gravel bars at the entrance to Chagvan Bay, and along tidal channels in the bay itself. Vertical relief in the area is generally less than 2 m and water depth in the bay and nearshore is very shallow (1-3 m), depending on tidal conditions and proximity to drainage channels. The 18 m isobath is about 16-18 km (W) from shore. Harbor seals have also been reported to haul out off the mouth of Goodnews bay. However, the exact proportion of harbor vs. Spotted seals is unknown. No map of Goodnews Bay has been prepared.
Quinhagak	Harbor seals haul out on beaches and sand and mud flats exposed at low tide at the mouth of the Kanektok River. Vertical relief in this area is generally less than

Continued. . .

Table 4.1. Continued.

Rookery	Physical Characteristics
Kuskokwim Bay	<p data-bbox="654 419 1452 540">1-10 m, depending on distance from shore and tidal conditions. Water depth near shore is generally less than 3 m; the 18 m isobath is over 40 km from shore at this site.</p> <p data-bbox="654 576 1452 932">This is an important haulout area for harbor seals in the Alaskan Bering Sea. The seals haulout on a series of sand/mud bars at the mouth of the Kuskokwim R., especially at low tide. During spring, virtually all seals at this site at spotted seals; during July through freeze-up harbor seals are at this site. Vertical relief is normally less than 1 m and water depth varies with the tide (1-3 m). This is thought to be the most northerly haulout site in the eastern Bering Sea where harbor seal pups are born.</p>
Islands off Cape Avinof	<p data-bbox="654 974 1452 1293">The low sand and gravel islands and associated bars and mudflats off Cape Avinof (about 60 km W of Kwigillingok) are used by both spotted seals (spring) and harbor seals (summer). In particular, the Kwigluk Islands, Pingurbek Island, Kikegtek Island and Krekatok Island are used by harbor seals from July to freeze-up. However, the exact numbers of animals using these sites and sites farther north off Baird Inlet are unknown.</p>
Kongiganik/ Kwigillingok	<p data-bbox="654 1364 1452 1619">Theses haulout sites are located midway along the north coast of Kuskokwim Bay. Seals haul out on sand, mud and gravel beaches and flats exposed at low tide. Vertical relief in the area is generally less than 10 m along the coast. Water depth is variable depending on tidal conditions (1-5 m nearshore); the 18 m isobath is over 40 km (S) from shore.</p>
Nunivak Island	<p data-bbox="654 1719 1452 1910">This haulout site is located on the rocks, islets and protected beaches in the vicinity of Cape Mendenhall. Vertical relief at the Cape is about 75 m; adjacent to this area relief is generally less than about 20-30 m. The 18 m isobath is located about 2-5 km from shore to the S and W,</p>

Continued. . .

Table 4.1. Concluded.

Rookery	Physical Characteristics
	but the area to the E is considerably shallower (<18 m throughout).
St. George Island	
Near Dalnoi Pt.	Harbor seals haul out on rocks, ledges and beaches all around the Pribilof Islands , however, the site near Dalnoi Pt., at the extreme W end of St. George Island, often supports more than just a few animals. Vertical relief in this area is generally less than 10 m and waters are generally deep; the 18 m isobath is less than 100 m from shore at Dalnoi Pt.
Otter Island	Virtually all of the perimeter of this small rocky island (0.08 km ²) is used by harbor seals for hauling out. Boulder beaches, reefs and offshore rocks are dominant substrates. The E end of the islet is generally of low relief (<3-5 m), with the exception of a pinnacle rising to about 45 m. The W end of the islet rises to about 80 m and water depth within 2 km of the island is less than 40 m.

APPENDIX 5. DESCRIPTIONS AND MAPS OF PACIFIC WALRUS HAULOUT SITES IN THE EASTERN BERING SEA (Sources are many; see APPENDIX 8 for details).

Table 5.1. Descriptions of Pacific walrus haulout sites in the eastern Bering Sea.

Rookery	Physical Characteristics
Amak Island	Walrus haul out on the coarse gravel and rocky beaches on the NE side of this island. The beaches are relatively narrow (3-10 m), the vertical relief behind the site is over 500 m and the 18 m isobath is about 7.5 km offshore from the site.
<i>Port Moller</i>	In the past walrus have consistently hauled out on the beach near Wolf Pt. on Walrus Island, at Entrance Pt., Bear River (about 15 km up the coast from Entrance Pt.), Harbor Pt., on Deer Island and Point Divide. Vertical relief in these areas varies from 1-5 m except in major channels, depending on tide conditions, and water depth is generally less than 5 m; the 18 m isobath is over 7 km N of Walrus I. and over 25 km N of Harbor Pt.
Cape Seniavin	Walrus haul out on the gravel and sand beaches at this site. Vertical relief behind the 3 to 10-m-wide beaches varies from 5-20 m, and the 18 m isobath is about 4 km offshore.
Port Heiden	Walrus occasionally haul out on the beach near Strogonof Pt., at the western entrance to the Port Heiden estuary. Vertical relief in this area is about 1-3 m, and water depth offshore is generally less than 6 m out to about 1.5 km; the 18 m isobath is about 5 km offshore.
Egegik Bay	Walrus have hauled out in recent years on the sand and gravel spits and bars at the entrance to Egegik Bay. Vertical relief near these sites generally varies from 1-3 m and water depth is generally less than 10 m throughout the area. The 18 m isobath is at least 20 km from shore in this area.
High Island	Walrus haul out on the rocky boulder strewn beaches on this relatively large island in the Walrus Island group. Vertical relief immediately behind the haulout sites is generally 10-50 m, however maximum relief is over 300 m at some sites on the island. Waters are shallow around this island (1-5 m out to 2 km from

Continued. . .

Table 5.1. Continued.

Rookery	Physical Characteristics
North Twin Island	<p>shore); <i>the X8 m isobath is almost 40 km to the S of this site.</i></p> <p>North Twin Island is the northernmost of the Twin Islands, the southernmost of the Walrus Islands group in northern Bristol Bay. Walrus haul out on the gravel beaches and rocky slopes all around these islands. Vertical relief is 145 m. The 18 m isobath is <1 km north of the island and the 30 m isobath is <3 km from the island.</p>
Round Island	<p>This is a major terrestrial haulout site for walrus in the Alaskan Bering Sea. They haul out on the rocky beaches around the island. Vertical relief at most sites rises to about 300 m; the highest point on the island is about 400 m. Round Island is the farthest E of the Walrus Island group, which is generally situated in fairly shallow water (generally less than 10 m); the 18 m isobath is about 7 km E of the island.</p>
Cape Peirce	<p>In recent years, this site has regained prominence as a very important terrestrial haulout site for walrus. They haul out in two distinctly different habitats in the Cape Peirce area: along 2-4 km of extensive gravel and rocky beaches both N and S of Cape Peirce, and on the beaches and in the dunes near the entrance to Nanvak Bay. The rocky beaches vary in width from 3-20 m; vertical relief behind most of these sites is from 20-100 m and the 18 m isobath is about 5 km from shore. Vertical relief on the beaches and in the dunes near the entrance to Nanvak Bay varies from 2-10 m and waters are generally very shallow adjacent to the site, i.e., <2 m except in the main channel that drains the Bay.</p>
Cape Newenham	<p>Walrus haul out on the rocky gravel beaches on the south side of the Cape Newenham peninsula, and at the cape itself. Vertical relief at the site generally varies from 10 to 50 m with maximum relief in this area being over 200 m. Water depth is less than 18 m out to about 4-5 km from shore around the Cape.</p>
Security Cove	<p>Walrus haul out on the wide gravel and sand beaches in Security Cove. Vertical relief behind the site is generally less than 5 m near the shoreline; waters are</p>

Continued. . .

Table 5.1. Continued.

Rookery	Physical Characteristics
	less than 5 m in the Cove and the 18 m isobath is about 18 km offshore to the NW.
Goodnews Bay	Walrus haul out on the gravel and sand beaches on the spits at the entrance to Goodnews Bay. Vertical relief at these sites is generally less than 3 m and waters are very shallow (<5 m) out to 2-3 km from shore; the 18 m isobath is about 35 km offshore to the W .
Kwigillingok	Walrus haul out on the gravel and sand beaches at this site. Vertical relief behind the site is generally less than 10 m and water depth is variable, depending on tidal conditions. In general, waters are only 1-5 m deep within 10-15 km from shore; the 18 m isobath is over 40 km (S) from shore.
Nunivak Island	
Mekoryuk	Walrus occasionally haul out on the beaches and shoals adjacent to the village of Mekoryuk on the N side of Nunivak I. Vertical relief in the area varies from 1-10 m and the 18 m isobath is over 15 km to the NW.
Cape Etolin	This haulout site is located about 6 km N of the village of Mekoryuk, on the far N side of Nunivak I. Walrus haul out on the gravel and sand beaches and rocky shores on and adjacent to the Cape itself. Vertical relief in the area varies from 1-10 m, depending on the exact location where the animals are hauled out. Waters are relatively shallow throughout the area N of Nunivak I. The 18 m isobath is over 10 km to the W and about 4 km to the E of this site.
St. Matthew Island	
Cape Upright	This site is located at the extreme SE end of St. Matthew Island, along gravel and rocky beaches at the base of 500 m high cliffs. The 18 m isobath is within 200 m from shore at this haulout site.
Lunda Bay	Walrus haul out along the narrow gravel beaches and rocky slopes at this series of sites. Vertical relief varies considerably (30-250 m) depending on the exact location along this section of coast where the

Continued. . .

Table 5.1. Continued.

Rookery	Physical Characteristics
Cape Glory of Russia	<p>walruses have hauled out. Nearshore water depth is generally deep at this site; the 18 m isobath is about 1-2 km from shore to the N. <i>However, the area to the E of Lunda, near Lunda Pt.,</i> is relatively shallow; the 18 m isobath in this area is about 6 km offshore. Some walruses occasionally haul out 10 km W of Lunda Bay, along a section of beach that separates a large freshwater lake from the sea; relief in this area is less than 5 m, and the 18 m isobath is only about 1 km offshore at this location.</p>
Hall Island	<p>Walruses haul out on gravel and rough rocky beaches at this site. Vertical relief behind the site is generally less than 50 m but rises to over 400 m about 8 km S of the Cape along the E side of island. Waters are relatively shallow NW of the Cape, between St. Matthew I. and Hall I., but the 18 m isobath is only about 1 km NE of the Cape and waters deepen rapidly to over 40 m less than 3 km NE from the site.</p>
Egg Island	<p>Walruses haul out on the gravel and rocky beaches primarily on the N and E side of Hall Island, which lies immediately N of St. Matthew Island. Vertical relief behind these sites is generally 200-250 m and the 18 m isobath is about 1 km offshore to the E.</p>
Egg Island	<p>Walruses haul out on the rocky ledges and the few stretch of narrow gravel beach on this small islet in SE Norton Sound. Vertical relief on the islet is about *** m. The 9 m isobath is about 500 m from shore, and the 18 m isobath is over 60 km to the NW. Waters throughout Norton Sound are generally less than 18 m.</p>
Besboro Island	<p>Walruses haul out on the rocky ledges and gravel and rock beaches around this small island in E Norton Sound. Vertical relief varies from 75 m to more than 300 m on the island, and the 9 m isobath is about 2-5 km from shore. The 18 m isobath is about 15 km W of this island.</p>

Continued. . .

Table 5.1. Continued.

Rookery	Physical Characteristics
Cape Darby	Cape Darby is at the tip of a sharp peninsula that extends into northern Norton Sound. Walruses haul out along on gravel and rocky beaches on both sides and at the tip of the Cape. Bluffs and cliffs rising to over 300 m back most of the sites in this area. Waters are relatively deep (>18 m) within 1.5 km from shore.
St. Lawrence Island	
Chibukak Pt.	This site is used by several hundred walruses, primarily in the autumn. It is located about 3 km E of the village of Gambell (Northwest Cape). Walruses haul out on the rocks and boulders along a steep beach backed by a slope leading uphill to 300 m-high Sevuokuk Mtn. The 18 m isobath is only about 3 km offshore (to the north) at this site.
Kialegak Pt.	This site is used by large numbers of walruses, primarily in the autumn. It is located NE of Southeast Cape. Walruses haul out on the gravel and rocky beaches that are backed by tundra flats and low bluffs (2-5 m high). The 18 m isobath is only 1-3 km offshore. Walruses also haul out on the spit adjacent to Sekinak Lagoon, which is situated about 15 km NW of SE Cape.
Maknik	This site is situated along a stretch of sand and gravel beach on a spit adjacent to Maknik Lagoon, at the E end of St. Lawrence I. Vertical relief is low, generally less than 2-3 m, and the 18 m isobath is about 2-3 km (S) offshore.
Salghat	This haulout site is located on a stretch of gravel and sand beach at the NE end of St. Lawrence I. Vertical relief behind the site is generally low (2-5 m), and the 18 m isobath is about 2-3 km (N) offshore.
Punuk Islands	Walruses haul out on gravel, sand and rocky beaches on all three of the Punuk Islands, but North Punuk I. is used most regularly. An exceptionally large number of walruses hauled out in autumn 1978 all along the N, NW and W sides of North Punuk I, all of Middle Punuk I., and over most of the north end of South Punuk I (Fay and Kelly 1980). On such occasions walruses no doubt haul out far back from the beach, on lowland tundra habitats. Vertical relief is generally less than 2-8 m

Continued. . .

Table 5.1. Concluded.

Rookery	Physical Characteristics
	<p>on all three islands. One hill at the extreme W end of North Punuk I. is about 70 m high; this is the highest point on the islands. Water depth around all three of the Punuk Islands is generally less than 18 m 2-3 km to the E and W and 5-6 km to the S; waters are very shallow, generally less than 10 m, along a shelf 6-8 km wide that extends N all the way to St. Lawrence I.</p>
Sledge Island	<p>This site is located about 50 km W of Nome, in relatively shallow waters (<18 m deep) about 10 km offshore from the mainland. Vertical relief of this island is about 230 m. Walruses haulout on the narrow gravel and rocky beach on <i>the</i> NE side of the island.</p>
King Island	<p>Walruses haul out on gravel and rocky beaches at this site. Vertical relief is over 350 m at some locations and the 18 m isobath is about 25 km to the NW.</p>

¹ Counts reported in the literature were sometimes for an entire island and sometimes for specific sites on an island, as indicated.
² Braham et al. (1980) suggest that a minor rookery exists on Round Island; they pooled counts from Round Island with those from the large rookery on Ugamak Island.

Table 6.8. Reported counts of northern sea lions at haulout sites in the southern Bristol Bay region. Haulout sites at which <100 animals have been recorded are not included.

¹Sea lions are abundant in waters of N. Bristol Bay during May/June, and are found in association with the huge schools of herring that spawn at that time. Apparently only a small fraction of these sea lions haul out.

²These sightings (Cape Peirce 1985-1987) were mostly of animals in the water that were swimming north.

³L. Hotchkiss (in Frost et al. 1982) reported sea lions hauled out at Cape Newenham during the summers of 1980, 1981 and 1982, with numbers ranging from 100-1500,

Table 6.10, Reported counts of northern sea lions at haulout sites (not rookeries) on the Pribilof Islands.

¹ Otter Island is mainly used in winter (Kenyon 1962). This is reflected in the reported counts (above) that indicate higher numbers in spring than in summer.

² According to Kenyon (1962) the last pups born near Northeast Point were in 1957. There are no indications in the literature of pups having been born there in recent years, though it is possible that some have been.

³ A report of 2500-3000 sea lions near Dalnoi point in the 1960's is not in agreement with the statement in Kenyon (1962) that "In the summer of 1960, Riley estimated that about 1200 sea lions hauled out on St. George Island" (Kenyon and Rice 1961).

¹ Harbor seals are ubiquitous around all islands, though in relatively low numbers. They can be expected to haul out at innumerable locations not included in this table. This region has never been intensively sampled throughout the year.

² Reported locations are those facing the Bering Sea or Unimak Pass.

Table 7.2. Harbor seal haulout sites, Unimak Island to Kvichak Bay.

¹ According to O'Neil and Haggblom, significant reoccupation of hauling grounds in the Cape Peirce area did not occur prior to 1983. However, Frost et al. reported significant use starting in 1981.

² We have distinguished, arbitrarily between haulout sites that are regularly used (A) and those used irregularly (B). Walruses of both sexes and all ages use haulout sites in the St. Lawrence Island as they are migrating southward, primarily during autumn, ahead of the seasonally advancing sea ice. Dead and dying animals are commonly found.

³ Murie (1936) in Geist and Rainey (1936) discusses the presence of a former haulout site at East Cape, and stated . . . "It is a well known fact that in older days walruses hauled up in great numbers at both of these places [Punuk Island and East Cape] . . .". He further indicated that walruses frequented East Cape annually, "though in small numbers". The site referred to as East Cape is unknown to us; it might be Northeast Cape or Southeast Cape (=Kialegak).

⁴ Walruses, coming from the large, established haulout sites on Big Diomedé Island, 2.7 miles from Little Diomedé Island, have repeatedly tried to again establish haulout sites on Little Diomedé. To date, those pioneering efforts have been unsuccessful due to hunting and other sources of disturbance by people and dogs.

APPENDIX 9. GLOSSARY OF SCIENTIFIC TERMS

Definitions of the following terms are based on standard usage in the scientific literature. In the case of **pinnipeds**, terminology is not consistent in the scientific literature; as noted in Hoover (1988a: 161), "...**Criteria** used to distinguish rookeries and haulouts are unclear and different between regions. ...". In this report, we have used terminology that is appropriate and most relevant to the four species of pinnipeds considered in this study.

1. Pinniped Terminology

- Haulout Site** A specific location on land *or ice* where pinnipeds (and sea otters) climb from the water (i.e. haul out) to rest, breed, give birth, care for their young, **molt, and/or thermoregulate** (Bigg 1985; Hoover 1988a, 1988b; Sease and Chapman 1988).
- Rookery** A term used to define specific terrestrial **haulout** sites where adult male sea lions and fur seals rest, defend territories around females, and where breeding, pupping and nursing of young by females occurs (Fiscus 1986; Hoover 1988a). These sites are usually along beaches or rocky slopes near the water (Calkins and Pitcher 1983; Bigg 1985; Loughlin et al. 1984, 1986, 1987). In general, rookeries are located far from continental land masses (Bigg 1985).
- Hauling Ground** A term used to **define** sites where subadult male and some **subadult** female northern sea lions and northern fur seals congregate during the mating season (Gentry and Kooyman 1986; Merrick 1987). These sites are associated with rookeries but, especially in the case of northern fur seals, are usually inland and farther from the shoreline than rookeries (Kozloff 1986).
- Haulouts** A term used to define sites where northern sea lions haul out, generally to rest, during the non-breeding season (Hoover 1988a). This term is also used in a more general sense to designate any pinniped **haulout** site that is not a rookery (Bigg 1985; Hoover 1988a, 1988b; Sease and Chapman 1988).

2. ACOUSTIC TERMINOLOGY

Sound Level or Received Level, L_r

The sound pressure at an observation position expressed in logarithmic terms

$$L_r = 20 \log_{10} p/p_r \text{ (dB)}$$

where the reference pressure, $P_r = 1$ microPascal (μPa)

Source Level, L_s

The sound pressure at an observation position 1 m from an acoustic source (dB re $1\mu\text{Pa}$ at 1 m)

Transmission Loss, TL

The reduction in sound level with distance along a given acoustic path caused by spreading loss and absorption loss components

$$TL = L_s - L_r \text{ dB re 1 m}$$

Source Directivity, D

The change in acoustic output of a source as a function of aspect angle in both the horizontal and vertical plane. Generally expressed as a logarithmic ratio

$$D = 20 \log_{10} P/P_m \text{ dB}$$

where p is the pressure in a given direction and P_m is the maximum source pressure in a reference direction.

Sound Wavelength, λ (m)

$\lambda = c/f$, where c is the speed of sound (m/see) and f is the frequency (Hz).

Spreading Loss

The reduction in sound level caused by geometric spreading of sound energy, generally expressed as cylindrical spreading ($10 \log_{10}$ range) or spherical spreading ($20 \log_{10}$ range).

Absorption Loss, A_v

The reduction in sound level caused by volumetric absorption of sound energy by the transmission medium.

Reflection Loss (RL)

The reduction in sound level after reflection from an absorptive surface, expressed in logarithmic terms

$$RL = L_{ref} - L_{inc} \quad (\text{dB})$$

where L_{ref} and L_{inc} are the reflected and incident sound levels at 1 m from the reflection point.

Sound Speed Profile

The variation of the speed of sound as a function of water depth.

Grazing Angle

The angle between the sound propagation direction and a reflecting surface.

Critical Angle

The reflection loss is 0 for grazing angles less than the critical angle.

Shear Wave

A method of wave propagation in solid media wherein the particle motion is transverse to the direction of propagation. (In an acoustic wave the particle motion is aligned with the direction of propagation.)

Acoustic Ray Theory

A solution to the acoustic wave equation which considers sound propagating as uniform phase wavefronts along a path (ray) determined by the initial radiation direction from the source and the refractive properties of the medium; (similar to optical theory for light) useful for deep water and high frequencies.

Acoustic Normal Mode Theory

A solution to the acoustic wave equation which considers sound propagation as a series of acoustic standing waves (normal modes) which **match** the boundary and source conditions specified. The pressure contributions from a series **of** modes are added to give the total acoustic pressure at a selected observation point (similar to room acoustic theory); useful for shallow water and low frequencies.
